The operation for union of the patella is one which the doctor says has an increased risk. By the old method of treating fractures of the knee the patient usually got well. For my own part, I think this operation involves a great risk, which a surgeon ought to estimate at its just weight. There have been several deaths from wiring the patella. In all cases of compound fracture of the patella, it should be wired if there is difficulty in keeping the fragments together by the ordinary apparatus.

I would say that, perhaps, in some cases it should be wired by a surgeon who is a master of antisepsis, and to those who have not the facilities of carrying it out thoroughly I would say, be careful; you might sacrifice a life, whereas, by using the old method of treatment, you would be perfectly safe, and would save the patient, possibly, with a halt in the gait. In one thing I disagree with Dr. Buchanan, and that is the idea of leaving such a serious matter to the patient himself. I don't think any patient is capable of judging the dangers he runs in undergoing an operation of that kind. He knows nothing about the value of antiseptics in the treatment of wounds; he doesn't know that it is any

[1] See p. 399.

different to perform an operation with antiseptic treatment than without; and to leave the question to a man ignorant of such matters, without being able to tell him how much risk he runs, I do not think it proper or right. I think the surgeon in such a case should be the judge, and should say to the patient which treatment will be proper.

Dr Buchanan: I would like to say that the patient ought to have the first choice If he should say, "I consider my life of the first importance, I don't want it to be put in the slightest jeopardy," as any of you gentlemen might say, then I take it to be the surgeon's duty to say, "We'll do the best we can for you." But as this man says, "I am a laborer, my life depends on the usefulness of my limb; if I have a crippled limb I cannot make my living; how much risk is there?" I say to him, "I don't think there is one chance out of ten, probably not one chance out of twenty that you will die." And there are cases by the dozen where the conditions are as I have stated, and where the patient will say, "I will take that chance; give me the strongest limb, for I can't make my living without it." Under these circumstances I think that the man has a right to his choice, and I think we can give him some idea of the risk he runs by telling him how many in the long run lose their lives by the operation.

AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

Second Annual Meeting, at Washington, September 18, 19, and 20, 1888.

Edward L. Keyes, M.D., of New York, President.

After a brief address of welcome to the members, the President introduced Dr. Roswell Park, of Buffalo, who read a paper on

Pyæmia as a Direct Sequel of Gonorrhœa.

About a month before his admission to the hospital, the patient who formed the subject of the paper contracted a gonorrhœa. The discharge ceased after about two weeks, and a few days later swelling of one knee developed, which was treated by a physician for gonorrhœal rheumatism. When admitted to the hospital, one knee was greatly swollen, the other less so, and the symptoms were typhoidal. They increased in severity and ended in death. The autopsy revealed pus in several joints, and an abscess and erosion at the articulation of the clavicle with the sternum. The mesenteries were enlarged.

Cases of pyæmia as a direct sequel of gonorrhœa, Dr. Park said, were extremely rare. It had not been proved that the gonococcus could give rise to the sepsis. But he had examined and found the presence of septic microbes in all urethræ which he had examined, whether the discharge were evidently gonorrhœal or apparently healthy.

Clinical Observations on Gonorrhœa, with Special Reference to Etiology, Duration, and Treatment.

Dr. John P. Bryson and Dr. Edwin C. Burnett, of St. Louis, presented the paper. The authors believe that in order to obtain a true history of the course of gonorrhœa, only virgin cases should be studied; that following the course of such cases one can easily convince himself of its specific nature from the peculiarity of its clinical phenomena alone. Chief among the clinical phenomena in establishing it among the definite specific diseases, is a tolerably definite period of incubation, which varies from three to ten days. The gonococcus of Neisser is present in specific cases, and in such cases the inflammation is greater than in urethritis due to traumatism or chemicals, and complications, such as chordee, epididymitis, etc., are much more frequent; there is obstinacy to all treatment and a tendency to chronicity. The proneness of specific urethritis to indefinite chronicity has been overlooked by most surgeons and has led to great errors in prognosis and as to the value of topical treatment. The abortive treatment they regard as both inefficient and harmful. Local treatment of all kinds is not justified in the first and second stages. All local applications should be reserved for the third or declining stage. They recommend internal administration of remedies supposed to have germicidal value, and the restriction of the diet. The gonococcus of Neisser they look upon as an essential etiological factor.

Retro-injections in Gonorrhœa.

Dr. E. R. Palmer, of Louisville, opened his remarks by a reference to Dr. Brewer's paper read before the New York Dermatological Society, and one read before the Kentucky State Medical Society on the use of retro-injections in gonorrhœa; and said that according to his experience with the method, recently, it resulted in many cases for a time so nearly in a cure that it led

both patient and doctor into the delusive belief that the trouble was over. But after a time the patient would go to another physician or return for treatment. Consequently the speaker had found it best and necessary to resort to mixed local treatment, making the injections of a weak solution of bichloride of mercury (1–30000) and also employing a solution of boric acid or salicylic acid.

Dr. Sturgis, Dr. Bangs, Dr. Taylor, the President and those who discussed the paper coincided in the belief that as a rule gonorrhœa could not be cured inside of five or six weeks, and that then patients would still find the physician's aid necessary.

The Use of Nitrate of Silver in the Local Treatment of Chronic Urethral Discharges.

Dr. F R. Sturgis, of New York, in this paper, devoted a few remarks to the pathological appearances of the diseased mucous membrane in cases in which it is desirable to make the applications; he described a small endoscope through which he was enabled to make the applications just where desired, and thus avoid the pain to the patient and the injury resulting from the solution coming in contact with the healthy portions of the urethra. Applications frequently made of solutions of nitrate of silver of from twenty to forty, and even as strong as sixty grains to the ounce had in his practice soon changed the character of the lining membrane for the better and caused the discharge to cease entirely.

The Diagnosis and Treatment of Chronic Urethritis, with Demonstrations of Instruments.

Dr. Oberländer, of Dresden, Germany, sent this paper, which was read by Dr. J. A. Fordyce. It contained a description of an endoscope employed by the author, which made very excellent illumination of the diseased urethra. The appearances found in different degrees of inflammation received considerable attention, and in the latter part of the paper the author spoke in favor of dilatation in preference to cutting operations in overcoming the tendency to stricture. The dilator was like that of Otis's, and was covered with rubber. As soon as dilatation was made much could be effected, he said, by medication. Of injections, he gave the preference to bichloride of mercury and nitrate of silver. He had discarded the galvano-cautery and sulphate of copper.

The President, Dr. Taylor, and others present had found the use for the endoscope limited.

Connection Between Masturbation and Stricture of the Urethra.

Dr. Samuel W. Gross, of Philadelphia, in this paper added a large number of cases to those which he first published in 1887, calling attention to the fact that masturbation is a common cause of stricture of the urethra. The examinations were made of persons who had never had gonorrhœa nor an injury of the perineum. In nearly nine-tenths of all the cases there was a stricture, nearly always of large calibre, usually single, and situated near the orifice.

Dr. Weir admitted the common existence of coaptations of the urethra as described by Dr. Gross, not only in masturbators, but in others as well, and he could not attribute them to the habit of masturbation. In general, the other members who participated in the discussion agreed with Dr. Weir.

Dr. Gross replied that in these patients the urethra was extremely sensitive to the passage of instruments at the point or points of stricture, that the endoscope showed congestion, and that division of the coaptation near the meatus could be made and the tissue examined, showing that it was true stricture.

The Curability of Urethral Stricture by Electricity: An Investigation.

Dr. E. L. Keyes read the paper. He had been led to make investigations regarding this method of treatment because several patients who had consulted him were not willing to receive any other. Hoping to be convinced of the great value claimed for it, he had sought advice and instruction himself and through his assistant from Dr. Robert Newman, who had very kindly granted his request. Altogether there were seven cases, two treated by Dr. Keyes, one by Dr. Newman himself, in the presence of Dr. Keyes's assistant, Dr. Fuller, and the others by Dr. Fuller, in each instance Newman's method being employed. In no instance had any more benefit followed the use of electricity than would follow any ordinary dilatation. The pain which it occasioned, the necessity for putting the patient to bed, and the danger of perineal abscess which threatened, were to be noted.

A current of two and one-half milliamperes was harmless, but he believed that it also had no effect whatever; a strong current, he said, was fraught with danger. The case treated by Dr. Newman was not benefited, although Dr. Newman took a different view

of it. In one case, the resistance to the passage of the instrument was not due to a fibrous stricture, and here no claim could be made for the electrical treatment, unless in overcoming spasm

Dr. Watson, of Boston, had used Newman's method of employing electricity in six cases of stricture, without successful results; it had been unsatisfactory in the hands of Dr. Bangs, Dr. Sturgis, and Dr. Tilden Brown; and Dr. Chismore, after one success apparently due to electricity, had found it without benefit.

Notes upon the Prognosis of Organic Stricture of the Urethra.

E. Hurry Fenwick, F.R.C.S., of London, sent the paper. He said that in the obstruction offered to the overflow of urine by an unrelieved stricture, three muscular systems, the vesical, ureteric, and cardiac, became successively affected with hypertrophy. This increase of expulsory power was rarely of long duration, relaxation and atony taking its place. The cardiac condition was contingent upon the renal changes, which in their turn depended upon the failure of the barriers to backward pressure which healthy or hypertrophied vesico-ureteric muscles presented. Hence the importance of estimating the condition of these dyke-like muscles. Their energy or capacity might be appreciated by ascertaining the presence or absence of residual urine. The author gave the results of careful and systematic examinations of the residual urine in 75 cases of organic stricture, showing its relation to the prognosis of the disease. He thought such examinations should be made in all cases.

The Operative Treatment of Hypertrophy of the Prostate, with Stereopticon Demonstrations of Specimens, etc.

Dr. Francis S. Watson, of Boston, read the paper, and made quotations from the writings of surgeons of to-day, showing that professional opinion is at variance regarding the propriety of a radical operation of any sort in cases of hypertrophy of the prostate, and that at present no *rationale* underlay the operative treatment of the disease. The data, he said, were of two sorts, clinical and the collection of anatomical specimens, thirty-four in number.

He made three points, referring to the operation based on the specimens: One, the distance from the junction of the membranous and prostatic urethra to the most distant part of the median enlargement within the bladder, which he called the perineal distance; two, the form of the median enlargement; three, whether the bladder was of small capacity and non-distensible, or the contrary. On the nature of these three factors, he said, the choice of operation rested. If the perineal distance is not greater than two inches and three-fourths or three inches, the enlargement could be reached by the finger through the perineum and operated upon. If, however, the form of the median enlargement was very salient, approaching the pedunculated form, it would be better to approach it through the supra-pubic route, even though it could be removed through the perineum. Third, the distensibility or non-distensibility of the bladder made possible or impossible the supra-pubic operation with its modern technique of Petersen. In about two-thirds of the thirty-four cases the enlargement could have been approached through the perineal route, while in the other third the supra-pubic operation would have been necessary. Clinically, the mortality had not been greater than by palliative treatment, and the permanency of results had given much encouragement. The author had operated in two cases; in one the patient died of irritative fever, and in the other the patient was well after three weeks, and had remained free of his urinary and prostatic troubles.

Dr. Abner Post, of Boston, then read a paper on

Prostatotomy for Enlarged Prostate at the Age of Forty-two Years.

The exceptional features in this case referred to the age of the patient (forty-two years), the character of the growth (being very hard and smooth, but not cancerous), and to the question of the proper method of treatment. The growth he thought was a distinct fibroid. The obstruction to urination was overcome by perineal division of the hard growth, and the use of a drainage-tube for a time, which prevented re-closure and contraction at the severed portion. None of the specimen was removed for microscopic examination. The patient is well.

The History of the Filaria Hominis;

its discovery in the United States, and especially the relationship of the parasite to chylocele of the tunica vaginalis. Dr. W. M. Mastin, of Mobile, was the author of this exhaustive paper, which also included the history of a case originating in the U. S. observed by Dr. Mastin. There was ground, he said, for the belief that a filarial

infested individual was rarely if ever in a perfect state of health.

Clinical Observations on Diseases of the Testicle.

Dr. L. B. Bangs, of New York, read a paper which contained the histories of three or four cases illustrating the difficulty of diagnosis and other points connected with diseases of the testicle. He believes that in far the greater number of cases inflammation of the testicle is due to direct injury or extension of inflammation from the prostatic urethra.

The question of removal of the testicle for tuberculosis having been raised, the President expressed the opinion that the tendency regarding extirpation was toward conservatism.

Dr. Bryson concurred in this opinion, yet there were cases, he said, in which removal of the tuberculous testicle was clearly indicated.

Dr. Taylor thought that it was rational and conservative surgery to remove the tuberculous testicle, which, if it remained, only encumbered the scrotum.

A Case of Removal of both Testicles for Recurrent Carcinoma.

Dr. Frank W. Rockwell, of Brooklyn, related the case, which was that of a man who applied for admission to the hospital early in January, 1887, having two months previously noticed a hard nodule in the right epididymis. The epididymis had reached about six times its original dimensions. Dr. Rockwell extirpated the testicle with the diseased tissue, the testicle itself not being involved. The disease was scirrhus. The following May the same condition appeared in the left epididymis although the lymphathics were not at all enlarged, and there had been no recurrence at the original seat of the disease. The left testicle with the growth in the epididymis was removed, the testicle being free from disease, the nature of the affection being scirrhus. When last seen in July the patient was entirely free from recurrence.

Some Points in the Differential Diagnosis of Bladder and Kidney Affections,

with demonstrations of the cystoscope and other instruments.

Dr. Alexander W. Stein, of New York, read the paper. The following questions, he said, often arose: Are the bladder symptoms due to renal disease? Are the kidney symptoms due to vesical disease? Are they independent of each other? And when one kidney is involved, which is the offending member?

It had become an axiom, he said, that the more remote the pathological encroachments were from the vesical neck the more tolerant was the viscus of their presence. On the other hand, remote and often insignificant causes excited the bladder to undue irritability, even though intrinsic lesions might be absent. In a large number of cases of vesical irritability in women in which the exciting cause was obscure, dilatation of the vesical neck afforded prompt relief. The advantages of the cystoscope were pointed out, but there were conditions in certain cases, he said, which interfered with its use. Passing to methods for collecting urine directly from one ureter, the author described a catheter which he had invented for this purpose on the end of which was a rubber bulb with a fenestrum which he had found by experiments on the cadaver could be introduced through the urethra and applied directly over the mouth of the ureter. He thought it would prove successful in the living subject.

Demonstration of a Perfected Evacuator and an Improvement in the Method of Removal of Débris from the Bladder.

Dr. F. N. Otis, of New York, read the paper, reviewing the history of the evacuator as developed by Professor Bigelow and the improvements by him and by Sir Henry Thompson and himself. He also exhibited the latest evacuators of Professor Bigelow and Sir Henry, and referred to the faults of others. The great difficulty had consisted in preventing the return of the débris into the bladder with successive aspirations. He declared that his own instrument was perfect in this respect, and required neither screen nor valve; that it now possessed a great advantage over that of Bigelow and Thompson in being about a pound lighter.

Surgeon-Major D. F. Keegan, of Indore, Central India, sent a paper on

Litholapaxy in Male Children,

which contained a table showing particulars of 114 litholapaxy operations performed on boys at the Indore Charitable Hospital, India, from December, 1881, to June, 1888. The mortality had been three and a half per cent.; of later cases, only one and three-quarters per cent. The average weight of the stones was 95 grains. The largest weighed in pieces over 600 grains. The average stay in the hospital had been six days. There had been, so far as was known, no recurrence.

Operations on the Kidney.

Dr. William H. Hingston, of Montreal, in this paper discussed more particularly nephrectomy, giving a brief historical review, and answering objections to the performance of the operation. The most difficult question of solution in the whole range of surgery, he said, is, What cases of renal disease are suitable for operative interference? Floating kidney had been mistaken, he said, for a diseased ovary; hydronephrosis for cystic tumor; cyst of the kidney for cyst of the ovary, for cyst of the liver, for carcinoma of the kidney, and so on. In one of his own cases, he had found it impossible while operating to say positively whether the tumor which he was removing was a tumor of the kidney or of the ovary. He recited some other cases from his own practice illustrating difficulty in diagnosis of affections of the kidney. In two or three cases, he had been able to distinguish between other tumors and a tumor of the kidney only by the presence of a limited resonance to one side of the umbilicus below the false rib. This was sometimes present in ovarian tumors, but very rarely so. The author claimed precedence in the removal of the kidney, having done the operation shortly before Simon, twenty years ago, the date of his operation being March 7, 1868. The tumor, a fibroid, weighing 15 pounds, was removed through an abdominal incision. The patient died before the completion of the toilet, the operation having occupied nearly three hours. Generally, the lumbar incision should be chosen.

Case of Nephro-Lithiasis, Complicated with Hydro-Nephrosis, in which Lumbar Nephrotomy was Performed.

Dr. Frank W. Rockwell, of Brooklyn was the author. The case illustrated in a marked degree the difficulties and uncertainties of exploratory operations as practiced in the lumbar region, and certainly for small calculi in normal or slightly diseased kidneys. The man first consulted him in the fall of 1887. When a boy he had suffered from hæmaturia and a calculus had been passed. When seen by Dr. Rockwell he had renal colic, hæmaturia, and at times there was fulness in the right flank. Retention of urine occurred more than once. Dr. Keyes saw the patient in consultation, and advised, if other measures failed, an exploratory operation. The posterior incision was chosen, and performed in December. There was much difficulty in reaching and palpating the kidney. At one time Dr. Rockwell thought he felt a hard substance in the kidney, but was unable to feel it again, and the wound was dressed. The patient continued to suffer until the latter part of January when much relief followed the passage of a stone. Again in March another fragment was passed, but he had not yet entirely recovered from his former symptoms. Dr. Rockwell thought that if what he felt during palpation of the kidney was the stone, he had probably hastened its passage down the ureter.

Discussion on Papers of Dr. Hingston and Dr. Rockwell.

Dr. Parks, of Chicago, exhibited a renal calculus removed by lumbar nephrotomy. He first saw the man last May, and learned that he had suffered from intermittent attacks of pain and symptoms of renal calculi for ten years, the pain always being referred to the neighborhood of the left kidney. The symptoms in general pointing to renal calculus, he performed lumbar nephrotomy. There was great difficulty in fixing the kidney so as to palpate carefully it. He punctured the kidney in various places, but was still unable to feel the stone, and was about to give up the operation, when he again introduced his hand and on the posterior surface of the kidney felt a hard substance. The stone was rough, had numerous facets, and was grasped tightly on all sides, but he was enabled to remove it by a pair of slender forceps. The man made a good recovery and was quite relieved. He had performed nephrectomy in one case, removing a tubercular kidney as large as a man's head through a lumbar incision which was extended around in front of the anterior superior spinous process of the ilium, the point of the last rib being tilted out of the way. Regarding the diagnostic significance of the circumscribed area of resonance referred to by Dr. Hingston, he with others had mistaken an ovarian tumor for a diseased kidney because of the presence of resonance limited to the inferior right iliac region.

Sir William MacCormac mentioned the case of a young man who had symptoms of renal calculus sufficiently distinct to lead a surgeon in St. Bartholomew's to undertake nephrotomy by the lumbar incision, but no stone was found. The patient afterward came under his care at St. Thomas's, when the symptoms were very severe; but in view of the negative results of the former operation he hesitated to interfere. He sent the

patient away, but he returned after a time, and as the pain was referred more particularly to a point corresponding to about the middle of one ureter, he explored this canal, but found nothing and closed the incision. He learned that the patient afterward passed an examination for admission to the army, and was then perfectly well.

The speaker then related three cases of injury to the kidney and sought the advice of those present. Three boys had been run over in the streets of London, and suffered, he presumed, a rupture of the kidney, which was followed by a large hydro-nephrosis. In each one the tumor occupied the whole flank, extending to the median line. One boy after several tappings of the tumor, which contained urine, recovered. In the second case the tapping was continued about a year, but failed, and he then made a drainage opening, but this failed, and the sinus did not close, and lastly he removed the remains of the kidney and the boy got well. The third case was still uncured; aspiration of the tumor had failed, and the question arose, should drainage be attempted, or should the kidney at once be removed? It was because of the trouble from the fistula which was made for drainage and afterward refused to close that the kidney was removed in the second case.

Dr. Fred Lange, of New York, discussed the choice of operations. He had never operated for tumors of the kidney. He had removed the kidney the seat of pyo-nephrosis, and in these cases he would always choose the lumbar incision to avoid septic infection of the peritoneum. In some other conditions the anterior incision might be preferable. Much care should be taken not to break off any facets in removing the stone from the kidney for evident reasons. He had devised some instruments for its safe removal. It was surgical vandalism to extirpate the kidney for symptoms of renal calculus so long as there was a possibility of removing the stone alone. The stone might be in the opposite kidney from that to which the symptoms had been referred.

Dr. Gill Wylie, of New York, had operated upon the kidney seven times during the past four years, in two cases cutting posteriorly and fixing the dislocated kidney, and in five cutting anteriorly and removing the organ. As to what cases should be operated upon, much would depend upon the subjective symptoms. If these were not severe, the patient would be likely to refuse an operation however much it was urged by the surgeon. As to choice of operations, he did not doubt that when the kidney was loose from its natural bed, or was enlarged, the anterior operation was the easier and safer. He had had no trouble from hæmorrhage or shock in the anterior operation. If there were strong evidences of pus, he would prefer the posterior operation. If he could not remove the kidney easily, he would close the wound, and subsequently make the anterior incision. A glass tube instead of a rubber one should be employed for drainage; the glass tube remained patent.

Dr. Ransohoff, of Cincinnati, had removed a hydro-nephrotic kidney through an anterior incision made for exploratory purposes, but the patient died of sepsis. He believed the anterior incision should be adopted in most cases, except when there was special danger of sepsis.

Dr. De Forest Willard thought that if the diagnosis was not pretty positive, the anterior incision should be chosen.

Dr. R. F. Weir, of New York, had done two nephrectomies, three nephrotomies, and had had one case similar to that narrated by Dr. Rockwell. In this case the kidney was thoroughly palpated, but no stone could be felt, and the operation was abandoned. Within twenty-four hours afterward, the patient was entirely relieved, and the urine was changed only in being somewhat bloody and containing a large number of uric acid crystals. He was rather loth to believe, therefore, that the trouble was due to only a recently-formed calculus. Yet it was known that the handling of the kidney in searching for a stone, none being found and none being passed, had in several instances resulted in relief of the patient. Regarding Sir William MacCormac's case, he suggested giving the patient the trial of drainage before proceeding to nephrectomy. While he agreed at present with Dr. Lange in his preference for the posterior incision in cases of danger from sepsis, yet his conviction was not so firm but what he might soon change it. Might not the peritoneum, he asked, be stitched to the edges of the wound in a way to prevent danger of septic matter entering its cavity?

Dr. Annandale, of Scotland, had cut down upon the kidney and palpated for stone in a number of cases, and, finding none, closed the wound. Yet the patients, excepting one, had afterward been relieved of their symptoms.

The President was of the opinion that in Sir William's case he would remove the

kidney at once, since the attempt at drainage had resulted so unsatisfactorily in the first case.

Dr. G. R. Fowler, of Brooklyn, had, in the case of a woman suffering from nephrolithiasis, made an abdominal incision and palpated the kidney, but discovered nothing. Her sufferings increased after a year, when he made a lumbar incision over the left kidney, but again found nothing. After the second exploratory operation, however, the patient's symptoms disappeared.

The discussion was closed by the authors.

On the Effects of Rapid Changes of Altitude in an Advanced Case of Interstitial Nephritis.

Dr. George Chismore, of San Francisco, read the history of the case, that of a man who had peculiar aggravation of conditions related to his kidney affection when reaching the high points in the mountains on a journey from San Francisco to New York, in which latter city his case terminated fatally. The paper was a pioneer one in this line of investigation.

Résumé of an Experience of Seventeen Years with the Operation of Dilating Urethrotomy.

Dr. F. N. Otis, of New York, in this paper, traced the successive improvements made in his dilating urethrotome since its invention in 1872, showed the advantages of this method of treatment over previous and other more recent methods, and the discoveries which it had led to, as to the relative size of the penis to the urethra. He had used the dilating urethrotome in more than a thousand cases, and had never had a death nor abscess result. He used only the short straight instrument, and pointed out the dangers of the other, which instrument makers would not take off the market. The incision should be exactly in the median line on the roof, not the lower surface. As to the radical cure of stricture by this treatment, he had tabulated a number of cases which he had been able to trace some years after the operation, and in a large percentage there had been no recontraction. The first case he ever operated upon with the dilating urethrotome presented recently the same size of the urethra as after the operation years ago.

Stone in the Bladder in Connection with Splenic Leucocythæmia.

Charles Williams, F.R.C.S., Norwich, England, sent the paper. The tendency to rapid formation of uric acid stone in splenic leucocythæmia was suggested, and the dangers of operations because of liability to hemorrhage were pointed out. His patient was operated upon, and died some days afterward.

Case in which the Bowel Ended in the Urethra in a Child Aged Four Weeks; Relief by Operation.

Dr. Arthur T. Cabot, of Boston, presented the paper, the first part of which dealt with the embryonic development of the bowel and urethra, and the last part treated of the operation resorted to for forming an anus. Except when constipated, all the fæces passed through the anus since the operation.

Perineal Litholapaxy.

Mr. Reginald Harrison, of Liverpool, had found it desirable in certain cases of vesical calculus to revive an old operation —entering the bladder by perineal urethrotomy and distending the vesical urethra with the finger, introducing a forceps, crushing the stone, and removing the débris by flushing the viscus. This procedure had been indicated in some cases in which recurrence of the stone could be predicted with certainty were ordinary litholapaxy resorted to. A diseased condition of the bladder was often the cause of stone formation rather than purely a result, and treatment of the vesical affection by drainage, etc., was necessary to prevent recurrence of stone.

An Unusual Case of Urethral Calculus,

was the title of a paper by Dr. H. G. Mudd, of St. Louis. The patient, a negro over forty years of age, had a calculus in the urethra in advance of the bulb, which when removed measured three inches in circumference and two and a half inches in length, and weighed 281 grains. Other smaller stones were situated in the membranous urethra. A small stone had probably lodged in the urethra two years before, forming the nucleus of the large stone. The patient regained his health.

Syphiloma of the Vulva

was the title of a paper presented by Dr. J. Nevins Hyde, of Chicago.

Election of Officers.

Dr. R. W. Taylor, of New York, was elected *President;* Dr. J. P. Bryson, of St. Louis, *Vice-President;* Dr. A. T. Cabot, of Boston, *Secretary.*

The next meeting will be held at Newport, sometime in May, 1890, the exact date to be determined by the Council.

Foreign Correspondence.

LETTER FROM SYRIA.

Since coming to the East some ten months ago, I have often wished to have time to send you some description of many of the interesting things met with here, but my time up to this moment has been too fully occupied to do so. Medical practice in this country is truly no sinecure. After arriving here in October, 1887, two months were taken up with a trip to Constantinople for the purpose of having my diploma *visé*. Here is situated the only legalized medical college in the Turkish Empire. No one is permitted to practice here until he has passed a satisfactory examination before the professors of this college. These examinations are conducted either in French or Turkish, as the candidate may desire. I had no difficulty whatever in obtaining an examination, which was conducted in a very fair manner, although I have heard many complaints from those who have applied for examination. The college building is a very dilapidated old structure standing outside of the business part of the city. The students seemed to be principally boys of from sixteen to twenty years of age.

I entered upon practice about the middle of January. It has been my custom to hold a clinic during the forenoon of five days each week. The number present at these clinics ranges from twenty to forty each day. Almost every variety of disease may be seen here—ophthalmia, the scourge of all eastern countries, is very prevalent. Rheumatism, also, which is largely caused by the damp ill-ventilated houses which the people occupy, is common. The only remedy that seems to have much effect here in the latter disease is iodide of potassium, in doses of fifteen to twenty grains a day. Both intermittent and remittent fevers prevail largely, and are frequently very obstinate.

There is one thing an American has to learn over again when he comes to this country to practice, and that is, the amount of cathartic medicines to administer. The ordinary doses recommended by our text-books are utterly useless here. From six to ten compound cathartic pills is an ordinary dose; and so are the following: from ten to fifteen pills of elaterium, one-tenth grain; podophyllin, two to three grains; gamboge, fifteen to twenty grains; castor oil, ten to twenty drachms; Epsom salt, two ounces. It requires some little practice to make one feel safe in giving such doses, but smaller are useless, and even such doses as are mentioned above often fail and have to be repeated. I hope to have time during the coming year to report the treatment of some cases of interest.

The Reporter comes regularly and is a welcome visitor. It is just the thing for the busy practitioner, who has not time to read long and tiresome articles to get what he wants. It is eminently practical and to the point.

With kind regards and well-wishes for the success of the Reporter, I remain,

Yours truly,

Latakia, Syria, J. M. Balph, M.D.
August 10, 1888.
(Med. Miss. R. P. Church.)

Periscope.

Poisoning with Kerosene.

Dr. K. A. Norderling, in a communication to the *Medical Record*, July 21, 1888, says that he was called on June 29 to see a child, eleven months old, who had swallowed an unknown quantity of kerosene. He arrived in about ten minutes after the accident had occurred, and found the little patient in the following condition: There was drowsiness, which was on the increase; and she was feverish; pulse, 150, weak; respiration, 40; face and neck covered with perspiration, extremities cold. When the accident occurred, her mother heard her cry, ran to her help, and found her in a very cyanotic condition, with kerosene vapor coming from her mouth. All the mother did was to sprinkle water in her face. Upon Dr. Norderling's arrival he immediately administered all the milk the patient could drink, and then wine of ipecac, which in five minutes brought on vomiting. The kerosene could be easily seen floating on the top of the vomited matter like fat globules in a soup-dish. Before leaving, he told the mother to give the patient all the milk she could drink, and also to give her castor-oil. Next morning the mother told him that the child had had one movement of the bowels in the morning, but neither that nor the urine which was passed all right had any odor of kerosene. She had been very restless during the night, coughed a little, and moaned between times. At noon the fever was high, 104° F. in the axilla; the pulse weak, 150; and she was still in a drowsy condition. In the evening of the same day the patient was nearly without fever, and looking bright, and the next morning she was perfectly well.

Terebene in Bronchorrhœa.

Dr. John W. Martin, in a communication to the *Medical Press and Circular*, August 29, 1888, says that he has employed terebene in three cases of bronchorrhœa, with marked success. His first case was that of a woman 79 years old, who had an attack of right hemiplegia, followed by a severe attack of broncho-pneumonia. At the decline of the inflammatory stage profuse bronchorrhœa set in, accompanied by a state of great exhaustion. A variety of treatment failed to give relief. In addition to the bronchial discharge there were urgent digestive troubles, dyspepsia, flatulent distension of the stomach and intestines, causing much inconvenience to the action of the heart, and seriously interfering with the administration of proper nourishment. The urine was free from albumin. Terebene was first ordered dropped on a lump of sugar, but this proved to be disagreeable to the patient, so that the following formula was substituted:

Gum terebene,	
Spir. chloroform	āā ♏x
Mucilage of tragacanth	f℥i
Syrup	f℥ss
Water	q. s. ad f℥i

Dr. Martin states that from the day the terebene was ordered there was a steady improvement of a most marked character. Of the other two cases one was a man, about 40 years old, suffering from passive broncho-pneumonic congestion, attended by profuse expectoration. The patient was very weak, and no treatment seemed to give relief until he was placed upon terebene. Immediate benefit was apparent. Marked diminution was noticeable at the end of twenty-four hours, and expectoration ceased within three days. The further progress of the case was in every way satisfactory. The third case was that of a wine merchant's traveller, who had, at the outset, acute broncho-pneumonia. When the acute symptoms subsided, profuse expectoration remained a very troublesome symptom. Various remedies failing to check this discharge from the lungs terebene was ordered by Dr. Martin with rapid and most beneficial results. The expectoration almost disappeared at the end of the third day, and the patient steadily improved. In prescribing terebene or turpentine, he regards it as necessary to be careful to examine for kidney mischief. If such is present, he would regard it as a contra-indication to the use of terebene.

Medico-legal Aspect of Wounds of the Heart.

M. Sal. Charrin, says the *Bulletin Médical*, July 29, 1888, has written an interesting thesis based upon the case of a young man who had received a stab wound of the heart, and who, before death, was able to talk, and to run ten metres (about eleven yards). At the autopsy it was found that the point of the instrument had penetrated the sternum at the lower border of the third rib on the right side, and opened the right ventricle at its lower part.

The question of surviving such a wound may be very important from a medico-legal point of view. Upon the fatality of wounds of the heart the author gives the following conclusions: In spite of their gravity wounds of the heart may in certain cases be survived a variable length of time, and permit the patient to talk, to defend himself, and in a word to perform voluntary acts. Statistics show that the fatality of wounds of the heart varies with the part of the organ injured. Wounds of the right ventricle, which are the most frequent, are less dangerous than on those of the left, and the latter are less grave than those of the auricles. Statistics show also that this fatality varies with the nature of the vulnerating body. Wounds of the heart made with pointed instruments are the least dangerous; then come wounds by cutting instruments, by fire-arms, and last, wounds of the heart as the result of contusions.

Researches upon Yellow Fever.

At the meeting of the Academy of Medicine of Paris, July 24, 1888 (*Gazette Hebdomadaire*, July 27, 1888), Dr. Gibier announced the result of the researches which he had made at Havana into the etiology and treatment of yellow fever. He finds that the blood, urine, bile, the pericardial cavity, and the viscera (except the intestines) of persons affected with yellow fever do not contain, in the great majority of cases, any micro-organism. On the contrary, the intestine contains a black or dark material, which is more or less abundant and toxic. M. Gibier has isolated from this a bacillus which seems to play an important part in the coloration of the substance, if not in the origin of the disease itself. From this it follows that the most rational treatment consists in repeated purgation and the use of intestinal disinfectants. This treatment is said to have succeeded in a grave case.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

SURGERY OF THE BRAIN AND SPINAL CORD.

Among the triumphs of modern surgery none have been more brilliant than those achieved in dealing with injuries and diseases of the brain and spinal cord. The time was—and not so very long ago—when these structures were considered almost beyond the reach of surgical skill. Those who are familiar with the history of surgery know that some very remarkable operations were performed upon the cranium and membranes of the brain more than a century ago; but these were rare events and very different from the deliberate and carefully designed operations of the present day. Modern surgery of the brain and spinal cord may be said to date from the year 1861, when Broca laid the foundation of what is now known as cerebral localization, and to owe its present position to the labors of Hughlings Jackson, Fritsch and Hitzig, Ferrier, and Charcot. Their studies have now become the property of all well-instructed surgeons, and in every part of the civilized world surgeons now approach the brain with a confidence and success which a few years ago would have been thought to be incredible.

It is not so astonishing, then, to find one like Macewen, of Glasgow, reporting, as he did in his address at the recent meeting of the British Medical Association, twenty-one cases in which he had operated upon the brain for surgical lesions, although this number is relatively and absolutely a very large one. But the pride of surgeons will be aroused when they learn that after these operations there were eighteen recoveries and only three deaths.

The address in which Dr. Macewen reports these cases is one of the most interesting and instructive pieces of surgical literature which has appeared for a long time. In it he traces succinctly the history of brain-surgery and describes with great clearness the principles which should guide the surgeon in ascertaining the nature and extent of the lesion present and in operating upon the patient. The magnificent results obtained of late years are due, to a great extent, to the general adoption of antiseptic and aseptic methods in performing surgical operations. These it is which have emboldened the operator to apply the teachings of experimenters and students of pathology; and these have enabled surgeons to approach the brain and spinal cord with a confidence like that which they enjoy when operating in these last days on organs within the abdominal cavity.

Thus, keen observation and refined skill have contributed to make brain-surgery one of the highest achievements of the present day; and it may be hoped that with added experience the results attained in days to come will far surpass those which even now have done so much to elevate our art and to relieve the sufferings of our fellow-men.

ARTIFICIAL FOOD FOR INFANTS.

It is universally accepted that milk is the proper food for infants; and when they are deprived of their mother's milk, the problem is, to substitute for it milk which differs as little in composition, digestibility, and nutrient qualities as possible. For practical reasons cow's milk has been generally employed. Chemical and physiological investigation, and clinical observation have apparently established the differences, in composition and properties, between human milk and cow's milk. These differences have occupied the attention of investigators, and various methods, familiar to the profession, have been suggested for overcoming them. The excess of casein in cow's milk is usually overcome by the addition of water, and the lack of fat and milk-sugar in the mixture is supplied by the addition of cream and sugar. The acidity of the cow's milk is neutralized, or its alkalinity increased, by the addition of lime-water, as recommended by Meigs and others, or by a solution of carbonate of sodium, according to the formula of Vogel. J. Lewis Smith states that the alkali serves the further purpose of preventing the formation of large curds in the infant's stomach, by retarding the coagulation of the casein. The method of Dr. Frankland accomplishes the same result in a different way. The cream from one-third of a pint of milk is added to two-thirds of a pint of whole milk; the skimmed milk is treated with rennet, the whey separated, strained, and boiled, and the whey, together with one hundred and ten grains of sugar of milk, is added to the mixture of milk and cream. As our readers will see, this plan is similar to that so strongly recommended by Dr. Wood in the REPORTER of June 30. By any of these methods a compound is obtained which is very similar to human milk in chemical composition.

Unfortunately, cow's milk, even when thus treated, is not digested as easily as human milk. This is believed to be due principally to the fact that the casein of cow's milk tends to coagulate in the infant's stomach in the form of a large curd, while that of human milk coagulates in fine flocculi, which have the mechanical advantage of presenting a greater surface for the action of the digestive secretions. The use of an alkali to overcome this property of the casein of cow's milk has been mentioned; Jacobi recommends prolonged boiling of the milk, and the use of barley-water as a diluent, instead of water; Smith adds to the milk some farinaceous article, as grated "flour ball," in order to mechanically separate the particles of casein; others use the Liebig's food, kept in the shops; and last of all the extract of the pancreas of the pig has been used to partly pre-digest the casein, and thus accomplish the same result. Nevertheless, the annual slaughter of the innocents continues.

We are fully convinced that the workers in this field have accomplished much that is of value, and that they have placed the subject upon a scientific basis. At the same time, we believe that the experience of physicians practicing in rural districts, and the results of recent chemical and microscopical investigations, show that heretofore the subject has not been fully appreciated. In the REPORTER, August 11, Dr. Chenery gives his own experience and that of Dr. Lynde in support of the statement that, in the country, the feeding of infants upon cow's milk does not greatly imperil their health or lives. The result of the examinations of the feces of infants fed upon cow's milk, by Escherich, Uffelmann, and Forster, go far to show that the prevailing opinion with reference to the relative indigestibility of the casein of cow's milk is much exaggerated. These considerations, and the fact that artificial food agrees with infants relatively well in winter as compared with summer, appear to us to strongly support the recent view that an undue prominence has been given to the exact chemical composition of artificial food

for infants. From the same premises, the conclusion seems plain that it is the condition of the milk, as much or more than its chemical composition, which determines its utility as a food for infants. Else why the difference in results obtained in city and country, and in winter and summer? It is well known that milk found in cities differs from the fresh milk of the country, barring adulteration, in having undergone greater or less fermentative or putrefactive changes.

Since these facts seem to be well established, the next advance in infant feeding, in cities, must be made by improving the quality of the supply of cow's milk, or by rendering practicable the substitution of the milk of some other animal, as the goat, which can be obtained fresh when needed.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

EXCESSIVE VENERY, MASTURBATION, AND CONTINENCE. By Joseph W. Howe, M.D., Etc. 8vo, pp. 299. New York: J. H. Vail & Co., 1888.

The book before us is of a kind which, if written with judgment and a clean instinct, might be useful; but, unfortunately, we fail to discover evidences of either of these important qualifications in it, and, therefore, cannot see how it can accomplish any good. Like most books on sexual depravity, it presents a disgusting subject in a repulsive way. Added to this, it perverts facts which are bad enough in themselves, and makes statements which are utterly false. It contains stories which have nothing attractive about them but their nastiness, and which will appeal only to prurient minds. That the book has come to a second edition is a proof that the author and publisher find a market for such wares—a fact to be deplored by all who regard decency as an essential characteristic of the medical profession.

It is quite possible that the author may have written this book with a worthy purpose; but, if this was the case, his effort has been an unfortunate one, and should serve as a warning to any other writer who may be tempted to enter the same unsavory field.

PTOMAINES AND LEUCOMAINES, OR THE PUTREFACTIVE AND PHYSIOLOGICAL ALKALOIDS. By Victor C. Vaughan, Ph.D., M.D., Professor of Hygiene and Physiological Chemistry in the University of Michigan, etc., and Frederick G. Novy, M. S., Instructor in Hygiene and Physiological Chemistry in the University of Michigan. 8vo, pp. viii, 316. Philadelphia: Lea Brothers & Co., 1888. Price, $1.75.

In these days, every studious medical man ought to read carefully some good book on the ptomaines and leucomaines, which play such an important *rôle* in the production of disease, but which, until very recently, were almost entirely unknown. Some admirable works on this subject have appeared within the last year or two in Europe, especially in Germany; but it is fortunate that our own country has not lacked men thoroughly fitted to investigate them, and to report to their brethren not only what has been learned about them abroad, but also what they themselves have discovered. The book before us is unquestionably the book for American physicians, and we may congratulate not only the authors and publishers of it, but also the whole profession of our land, that such a book has been prepared and put out at so moderate a price.

Like all the publications of Lea Brothers & Co., this book is issued in very handsome shape.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

A Brief History of Proceedings in the Medical Society of Pennsylvania . . . to procure the recognition of women physicians, etc. To which is added an account of the measures adopted by the Society . . . to procure a law to authorize trustees of hospitals for the insane-poor . . . to appoint women physicians to have entire control of the insane of their sex. By Hiram Corson, M.D., Conshohocken, Pa. Philadelphia: Jas. B. Rodgers Printing Co., 1888. 8vo, 40 pages.

—This interesting pamphlet contains an account—written by the foremost advocate of the recognition of women as physicians in this country—of the struggles through which this cause has passed since 1858. It is a warm narrative, marked everywhere with the earnest purpose and determined resolution of its author, and is a valuable contribution to the history of medical politics in this State. It is to be regretted, perhaps, that the writer of it has not included an account of the recent election of a woman to membership in the Philadelphia County Medical Society, which, until recently, has been the most consistent and unyielding opponent to giving women the same recognition which is granted to reputable men engaged in the practice of medicine.

Literary Notes.

Science is a weekly periodical which devotes so much attention to matters of public health and medical progress that it is of exceptional interest for medical men. In addition to this, it contains, as might be expected, a great variety of valuable matter relating to other branches of science, and is an extremely useful compend of what is going on all over the world in these departments.

The Mid-summer Holiday Number of the *Cosmopolitan* contains a large number of excellent engravings, and an article on roses which is illustrated with excellent wood-cuts and beautiful colored plates. This is the only magazine, we believe, which uses colors in its illustrations, and those in the number under notice are more attractive than any which have yet appeared in it. An article on the "Ladies of the American Court" gives an interesting presentation of social life in Washington, and contains pictures of sixteen distinguished women of that city, Mrs. Cleveland naturally leading the number.

CORRESPONDENCE.

Ethics of Opium Habitués—A Reply.

TO THE EDITOR.

Sir: Your correspondent is greatly surprised that Dr. J. B. Mattison at this *late* date should reply to the objections made to his paper when it was read before the Society of Medical Jurisprudence, and which was noticed in the issue of the REPORTER of July 7, 1888. At the close of the Society's discussion, Dr. Mattison having the opportunity to answer his opponents merely remarked that he "stood" by what he had written.

Now that he has used the valuable columns of the REPORTER for the intention, perhaps, of crushing those who objected to his conclusions, we hope that we may succeed in demonstrating to the readers of this journal the errors which Dr. Mattison there presents.

Every authority, who has sincerely and conscientiously investigated the effects of the continuous use of opium upon the system, and who does not write in the interests of bringing opium habitués to his private asylum, or who does not pander to the perverted sentiments of his clientèle differs from Dr. Mattison. But it is not your correspondent's intention to show anything but the curious reasoning of the former gentleman. Dr. Mattison says that the general rule "that the general use of opium makes the male impotent and the female sterile" makes it difficult to conceive of *any* influence transmitted from generation to generation. In answer to this I would like to ask: Must the opium habitué be so absolutely impregnated with the drug before he makes an attempt to propagate his species? Has that habitué never had any sexual desire whilst taking the drug? If Dr. Mattison affirm the former and deny the latter we have nothing further to say than that his experience differs from that of every other investigator, and that his patients are singularly the demonstration of the rule and those of every other writer the exception. In the light of this it is remarkable that neurologists should have presented to their view cases of mental and physical defect in the offspring of parents addicted to the use of opium.

Let the latest work of the greatest of the authorities on this subject speak.[1] Erlenmeyer says: "There is a married couple in my practice of which both man and wife daily injected from 1 to 1.5 grammes of morphine for many years. She conceived from him and bore, after the usual period of pregnancy and in normal confinement, a vigorous child." Repeatedly has Erlenmeyer had the same experience with female habitués and of these cites no less than four among his fifty histories.

N. E. BRILL, A.M., M.D.

805 Lexington Ave., N. Y.

September 10, 1888.

[1] Die Morphiumsucht, 3d Edition, 1887, p. 44. Von A. Erlenmeyer.

Negroes and Chloroform.

TO THE EDITOR.

Sir: Is there a case on record of a *full-blooded* negro dying during the inhalation of chloroform? I have asked many physicians this question, and have been invariably informed that they knew of none.

Yours truly, R. P. HUGER, M.D.

Anniston, Ala.,

September 15, 1888.

NOTES AND COMMENTS.

Personal Identification.

A full report of a recent lecture on personal identification, by Mr. Francis Galton, appears in *Nature* for June 21 and June 28. Mr. Galton here presents a practical application of his favorite pursuit, the accurate description of physical and mental peculiarities. He proposes a very ingenious scale of divergencies from the normal for any one feature, and has even invented a mechanical device by which the tedious labor of arranging a large number of such observations can be much abbreviated. The anthropometrical laboratory, at which anyone can, under proper restrictions, have a record made of his chief physical measurements, is now open in London, and promises to yield valuable material for this line of study. In connection with this work, Mr. Galton has studied the striations of the human fingers, and is able to corroborate the value attributed to them as a means of identification. These markings are easily obtained, and the variety of them is larger than one would *à priori* imagine. The markings of a finger of Sir William Herschell, made in 1860 and 1888 respectively, are figured, and show a striking similarity. The difference in age of the two prints testifies to the wearing of the epidermis. The study is still in its infancy; but the success of such measurements for identifying criminals, as exhibited in France, promises to draw more general notice to the subject.—*Science*, July 27, 1888.

Quack Advertisements in Religious Newspapers.

The *Provincial Medical Journal* says: "A strong agitation has been started in America against the quack advertisements which appear in religious papers, and, in consequence of appeals made in the interests of morality, the respectable sectarian organs have declined to insert or renew those advertisements. A certain class of advertisements disfigure our English religious papers. It is to be hoped that they will copy the example set by their American co-religionists, and refuse them. Another class of advertisements are to be found in religious papers which do not offend against decency, but which are frauds. To promise a cure for incurable disease, or to offer a panacea which will cure all kinds of diseases, is to obtain money under false pretenses. A certain class of advertisements do this, and it must be known to the proprietors that these advertisements are dishonest and should not have a place in papers professing to teach morality."

Comparative Value of Codeine and Morphine in Diabetes.

Dr. J. Mitchell Bruce, in a communication to the *Practitioner*, July, 1888, gives the results of some experiments which he made in order to determine the comparative value of codeine and morphine in the treatment of diabetes. The experiments seem to have been conducted with great care, and show that morphine is to be preferred to codeine in the three respects of power, cost, and safety. The best effect was obtained from about six grains of acetate of morphine daily; from phosphate of codeine, not until about thirty grains (equal to twenty-one grains of codeine) were given daily. A patient consuming six grains of acetate of morphine a day would, therefore, considering the relative cost of the two drugs, be treated at about one-twelfth the cost of another taking twenty-one grains of codeine.

With regard to narcotic symptoms occurring under the use of morphine, Dr. Bruce says they have rarely presented themselves as long as the sugar continued to fall, when the drug was given every three or four hours by the mouth. He has found very decided evidence of the cerebral action of morphine in diabetes when the hypodermic method of administration was employed. He calls attention to the fact that the large size of the doses of these powerful drugs which are required restricts their general employment. The chief difficulty was found to consist in removing the last traces of the sugar, For instance, it required in the first case twice as much morphine a day to completely remove the sugar from the urine as it required to reduce it to 167 grains a day, which he regards as a comparatively safe excretion. He suggests that in routine practice a physician should be satisfied with this degree of success. He states distinctly, however, that the results which he has obtained refer entirely to the action of these drugs *plus* rigid dieting, as only by first establishing a sugar equilibrium by means of proper feeding can the real action of the drugs be ascertained.

United States Veterinary Medical Association.

The twenty-fourth annual meeting of the United States Veterinary Medical Association was held Sept. 18, in New York. Dr. Hoskins, of Philadelphia, for the committee appointed to secure a uniform standard of examination of veterinary colleges, reported that all but three colleges had agreed to extend the curriculum from two to three terms of six or eight months each. The three colleges which refused were those at New York, Chicago, and Toronto. The following officers were elected: President, Professor R. S. Huidekoper, of Philadelphia; Vice-President, W. B. E. Miller, of Camden, New Jersey; Secretary, W. H. Hoskins, of Philadelphia; and Treasurer, James L. Robertson, of New York.

Philadelphia Lying-in Charity.

The new hospital of the Philadelphia Lying-in Charity at the southwest corner of Eleventh and Cherry Sts., recently completed, is now open for the reception of patients. The building is a model of hospital construction. Married and unmarried women are cared for (during the lying-in period of their first confinements only) in the maternity wards and in private rooms. Private rooms and surgical wards for the treatment of diseases of women are in a separate and isolated portion of the building. Nurses are furnished to physicians at any hour of the day or night immediately and without charge. Physicians are invited to inspect the building, or if living at a distance to write for blanks for the admission of patients to Dr. Charles Meigs Wilson, Surgeon in Charge, southwest corner Eleventh and Cherry Sts., Philadelphia.

NEWS.

—Two refugees from a quarantine camp in Florida were arrested in New York on Saturday, September 22, and taken to North Brother's Island, where they will be kept by order of the Board of Health.

—In response to the call for volunteers of the order of the Red Cross, Dr. William Rickert left Baltimore for Jacksonville, Fla., where he will give his services for the relief of the sufferers from yellow fever. He leaves a family in Baltimore and abandons a remunerative practice.

—The *Lancet*, September 8, 1888, says that in the Tyrol there are so few applicants for vacant medical positions that in some cases these have to be given to students. The proprietor of a bathing establishment recently advertised for a physician for the summer months, offering board and lodging as remuneration. Not a single candidate presented himself.

—A new disease, according to the *Ledger*, September 19, 1888, is said to have affected the grape-vines of the Santa Ana and San Gabriel valleys of California. It is termed the "sapsour." The vines begin to wither and in a short time die. The disease is infectious, and spreads very rapidly. The best remedy thus far known is to dig up the vines as quickly as they show the blight, and burn them.

—Dr. George Dock has been elected Instructor in Morbid Anatomy and Bacteriology in the Texas Medical College and Hospital, Galveston, Texas. Dr. Dock is unusually well equipped for the position, both through his special studies upon these subjects in Germany, and in the Clinico-pathological Laboratory of the University of Pennsylvania, under Dr. Osler. His selection reflects great credit upon the judgment of the Faculty of the Texas College.

—Among the recent decrees made in France is one relating to the inspection of butter for the repression of fraudulent dealings. By this, special persons are authorized to take samples of butter in any place, whether the butter is exposed for sale, stored in a warehouse, or in transit by land or water. Each sample taken is to be subject to a special examination. Pure butter, mixed butter, margarine, oleo-margarine, and grease intended for consumption, in transit, must be contained in closed packages, and the origin and nature of the merchandise must be conspicuously specified thereon.

HUMOR.

Relieved in Mind.—Mother: "Oh, doctor! I'm so glad you have come. We have had such a scare. We thought at first that Johnny had swallowed a $5 gold-piece." Doctor: "And you found out that he didn't?" Mother: "Yes; it was simply a nickel."

"When does a man fail?" is a question that is being asked by the press with considerable freedom. A business man fails indeed when he fails to advertise; we have seen longer answers, but the above is complete in every particular and easily remembered.—*Hat Review.*

A Special Favor.—Bereaved Widow (to country editor)—"Do you charge for obituary notices, Mr. Shears?" Country Editor—"As a general thing, we do, Mrs. Bently; but your husband and I were very old friends, and I will only be too glad to publish his obituary for nothing."

An "In-growing" Town.—"Has the town grown much in the last ten years, Mr. Snaffles?" "Grown? My, yes! Why, this very lot we're standing on I paid $10,000 for in '72. I sold it in '81 for $2,000, and had to buy it back on foreclosure for $1,500. Stranger, you can see this town grow, but the trouble is it's an ingrowing town."

Anxious Mother: "You think he is out of danger now, doctor? He will get well?" Doctor: "No doubt about it at all, madam. The amputation has been completely successful." "And I warned him, oh! so carefully, to let toy cannons alone. Doesn't it look like a judgment on my poor boy?" "It does look like a judgment, certainly; and yet such things sometimes prove to be blessings in disguise. It is not for us to repine. One hundred dollars, madam. Thanks."

OBITUARY.

JOHN HENRY SMALTZ, M.D.

John Henry Smaltz, M.D., of Philadelphia, died September 22. He was born in Philadelphia in 1827, and was graduated from the College Department University of Pennsylvania in 1846. In 1849 he received the degree of Master of Arts, and in the following year was graduated from the Medical Department of the University. He was a member of the Northern Medical Society, the County Medical Society, the Pennsylvania State Society and the American Medical Association.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SOLUTION FERROUS MALATE.

(Amer. Phar. M'f'g Co.) 4 Grs. to Fluid Drachm.

DOSE —30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat, and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

Solution-Salicylate of Iron

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful four times a day.

An unfailing remedy in acute or chronic Rheumatism, where deformity has not yet resulted. Has also been prescribed with great satisfaction in other affections where Salicylic Acid, Bi-carb. Sodium and Ferrous Malate are indicated.

Ferrous Malate, Gentian & Cinchona

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

FOR THE INSANE.

CINCINNATI SANITARIUM.

PRIVATE HOSPITAL AND RESIDENCE.

(Incorporated 1873.)

Proprietary Interest Strictly Unprofessional.

Both sexes and all classes of mental and nervous diseases provided for.

Forty minutes by rail from C. H. & D. depot, Cincinnati. Address,

ORPHEUS EVERTS, M.D., Sup't.

COLLEGE HILL, OHIO.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

COMMUNICATIONS.

NOTES OF A CASE OF FILARIA MEDINENSIS.[1]

BY ARTHUR VAN HARLINGEN, M.D.,
PHILADELPHIA.

X., an *employeé* in the Custom House at Philadelphia was referred to me by Prof. D. Hayes Agnew on the 17th of January last.

The patient a man of 47 had never lived out of Philadelphia. He was accustomed to opening and examining invoices from all parts of the world, including the Orange Free State, but did not come in contact with any foreign goods. His health had always been good, and he had never suffered from any disease of the skin.

Some time in September last (four months previously) the patient first noticed a small red papule under the skin of the back of the hand. The lesion gave rise to considerable pruritus but no pain. It soon assumed an elongate form and began to develop at one end, taking on a serpentine form and pushing along under the skin throwing the epidermis up into a ridge, and showing beneath it like a sinuous red cord.

The worm, for such it appeared to be, progressed slowly over the back of the hand between the index and the middle finger and down across the palm, in which position it was when the patient consulted me.

The worm then presented the appearance of a deep red sinuous cord situated just beneath the skin, which was slightly elevated above it, five to six inches in length and about an eighth of an inch in breadth. The head of the parasite appeared to be near the radial side and just turning from the palm to the back of the hand.

There was little or no abnormal sensation due to the presence of the worm. Occasional attacks of itching were experienced, and when the patient washed his hands there was a good deal of burning in the palm.

Concluding from the appearances presented that I had to deal with a case of *Filaria Medinensis*, I cut down upon the parasite, hoping to demonstrate its presence and perhaps to remove it in the usual way by firm continued traction. For some reason or another, probably awkwardness, I failed to find the parasite on two successive occasions, and as it was making perceptible progress toward the back of the hand and as I feared that if irritated it might descend to deeper lying tissues and give rise to more serious trouble, I determined to employ the means which Horton terms the radical cure and which was also used successfully by Tilbury Fox, namely, the internal administration of asafœtida.

The patient was ordered to take three 3-grain pills four times a day, or thirty-six grains of asafœtida daily. After four days treatment the patient returned in a marvelously improved condition. The red, elevated, cord-like lesion wandering irregularly over the palm had given place to a withered brown trace, level with the skin or slightly depressed and totally without sensation, even when rubbed.

On the side of the hand, however, a portion about an inch in length retained somewhat the old appearance. It had turned

[1] Read before the American Dermatological Association, at the Twelfth Annual Meeting, Washington, D. C., September 19, 1888.

and bent downward toward the joint of the wrist.

The asafœtida was increased to forty-eight grains daily, and at the patient's next visit, five days later, only a trace of the original red line could be seen near the head of the parasite, all the rest was represented by a brown withered line.

I have not seen the patient since, but have been informed by Prof. Agnew that he has been and remains well, without further trouble from the dracunculus.

I have been led to report this case because it is an instance of a purely tropical or subtropical affection occurring in a temperate climate, and also because of the rapidity and certainty of the cure. So far as I am aware, but two cases of Filaria Medinensis have been recorded as occurring in this country in persons who have not been in tropical regions. One of these was reported by Surgeon Jarvis U.S.A., in the *Virginia Medical Monthly* for May, 1857, the other by Dr. N. S. Walker, of Georgia, in the *Southern Medical and Surgical Journal*, vol. 13, N. S., 1857, p. 463. The first of these occurred on the instep of an adult, and the worm was extracted by the knife. The second occurred in an infant three months of age, and was cured by repeated transverse incisions. The other cases reported in American journals have been those of persons returning from tropical climates. Occasionally, the Filaria Medinensis has been confounded with the Filaria Sanguinis hominis, that parasite which is conveyed by its intermediate host the mosquito, and which gives rise to chyluria, elephantiasis, etc.

The method of propagation of the Filaria Medinensis is unknown. It was formerly believed to be contracted by bathing in tanks where the minute Filaria swarm, or by walking barefoot in the mud. This view has been supported by the fact that the greater number, in fact almost all cases occur about the feet. But such a mode of penetration is unlikely and not in accordance with our knowledge of the mode of propagation of other parasites of a similar kind. The other theories are: First, that the worm is swallowed in drinking water directly; second, that it is swallowed in the body of an intermediate host, some minute aquatic crustacean. No adequate demonstration of the mode of propagation or of the invasion of the parasite has as yet been brought forward, and we must, for the present, confess our ignorance in this matter.

The description of the clinical appearances presented by the Filaria Medinensis in our text books is, I think, inadequate. Too much stress is laid upon the furuncle or abscess-like lesion in which the worm is found coiled, or from the bottom of which it protrudes. In many cases reported in the journals, on the other hand, it will be found that the whip-cord-like sinuous red line under the skin is the most prominent symptom, and also that there may be a number of these marks.

The treatment recommended for Filaria Medinensis is almost invariably that employed by the natives of those countries where this parasite abounds. It consists in cutting down upon the worm and withdrawing it by gradual and continued traction. Should the worm, which, it must be remembered, is a pregnant female teeming with myriads of living young, break, it is said that the young worms escape into the surrounding tissues and give rise to violent irritation and inflammation, occasionally fatal in its result. But this is by no means invariably the case. In one of the cases cited above, repeated section of the worm, even in an infant three months of age, was followed by no evil consequences, and, in fact, led to the cure of the disease. Injections of carbolic acid have been recommended by some authorities, and had been used in the case of my patient before he came under my care, but without a very satisfactory result. Electricity has been recommended, but I have not been able to find any case reported in which it has been employed. As regards internal treatment, two remedies have been employed with striking success. Martin, in a severe case, where there were a great number of the parasites in various parts of the body, obtained a very speedy cure by the administration of moderate doses of iodide of potassium. Dr. Horton (*Guinea worm or Dracunculus*, by Jas. A. B. Horton, London, 1868) used the tincture of asafœtida in thirty-drop doses three times a day, with "almost magical" effect in a number of cases. The drug seems to kill the parasite and its young almost immediately, and absorption takes place without any disturbance to the patient's system. The late Tilbury Fox employed asafœtida with success in one case, but I have not heard of its use by any one else. In the case I have reported, the effect of the drug was so striking that I think it should be enrolled among the list of remedies against Filaria Medinensis, and employed in preference to the surgical treatment.

CASES OF DISEASE OF THE APPENDIX AND CÆCUM.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

I have recently had occasion to look over my notes of cases of disease of the cæcum and appendix, and the following records illustrate the anatomy of some of the commoner affections of these parts:

ANOMALIES OF POSITION.—The appendix is extremely variable in position and may be found very far from the right iliac fossa. I have seen it in every region except the left hypochondriac and the left lumbar.

Case I.—Phthisis. Cæcum, appendix, and the first parts of the ascending colon unattached. The cæcum with a short appendix was turned up and lay in close contact with the gall-bladder, separating it together with the edge of the liver from the right costal margin. There were no adhesions; it could readily be replaced.

Case II.—Cirrhosis of liver. Man, aged 31. The appendix passes behind the cæcum and is adherent on the peritoneum covering the right kidney. There had been an old localized peritonitis.

Case III.—Pneumonia. Woman, aged 40. Appendix long and descends into the pelvis, where it is firmly attached to the broad ligament, near the ovary, forming a noose, about an inch in diameter.

Case IV.—Male, aged 68. Old peritoneal bands join several of the coils of intestine together. The cæcum and appendix with the ascending colon are drawn up and to the left, the cæcum folded on the colon, and the valve and appendix occupy a position corresponding to a point 1½ inches below and a little to the right of the navel.

Case V.—Typhoid fever; perforation. Woman, aged 25. A long appendix passes vertically down into the pelvis and is attached to the wall of the pelvis not far from the ovary.

I dissected two cases recently, at the Philadelphia Hospital, in one of which the appendix was adherent to the ovary, and in the other to the broad ligament.

Case VI.—Appendix very long, passes behind the cæcum and ascending colon, and the lower end of the right kidney, reaching almost to the pelvis of that organ.

Case VII.—Typhoid fever. "In removal of intestines the appendix is found to occupy a very unusual position. It passes behind the cæcum and ascending colon, along the anterior surface of the kidney, close to the hilus, and its apex is in close proximity to the under surface of the right lobe of the liver, being distant 1½ inches by measurement from the gall-bladder."

ULCERATION.—This is a not uncommon lesion in phthisis and typhoid fever. No doubt the following list would have been greatly increased had a more systematic examination been made of the appendices in all cases.

Case I.—Girl. Phthisis—pneumothorax. Ulcers in cæcum; appendix dilated; mucosa extensively ulcerated.

Case II.—Phthisis. Male, aged 18. Much recent swelling and ulceration of Peyer's glands in ileum. The appendix large, the mucous membrane swollen, congested; it presented one small ulcer. There were three oval fæcal concretions in the tube.

Case III.—Typhoid fever. Girl, aged 17. Many ulcers of ileum, and small ones in cæcum. Several small ulcers at, and just within, the entrance of the appendix, the mucosa of which was greatly swollen.

Case IV.—Man, dead of typhoid fever. Extensive ulceration of cæcum. "In appendix vermiformis, mucosa at distal end much swollen, and there is an ulcer the size of a five-cent piece with the slough still adherent."

Case V.—Phthisis. Woman, aged 29. No ulcers in ileum, cæcum, or colon. Appendix large, swollen, and unattached. It contains soft fæces, and half an inch from the end there is an irregular ulcer the size of a five-cent piece.

Case VI.—Phthisis. Woman, aged 19. Ulcers in ileum and one in cæcum at valve. Appendix dilated and large, particularly the distal end. When slit open, mucous membrane swollen. Two tuberculous ulcers at the extremity.

Case VII.—Phthisis. Male, aged 36. Ulcers in ileum, cæcum (very extensive), and colon. Appendix large and thick, adherent on iliac fascia. Several ulcers, and at its extremity a small localized abscess the size of a walnut, due to perforation of one of the ulcers.

Case VIII.—Ann W., aged 22; typhoid fever. Cæcum lies in pelvis, no attachment; the peritoneum covers it completely; the appendix ascends from tip of cæcum to the margin of the pelvis and ends in a fibrous cord just under the meso-colon. Much ulceration in cæcum; in appendix several ulcers with adherent sloughs; mucous membrane much swollen.

Case IX.—Ellen R., aged 16; phthisis. Extensive ulceration in ileum and cæcum; appendix swollen; mucous membrane tumid and extensively ulcerated.

Case X.—Male, aged 28; typhoid fever. No ulcers in the cæcum. In the appendix, which is long, the mucous membrane is swollen, and there are two ulcers with adherent yellow sloughs.

Case XI.—Male, aged 35; phthisis; University Hospital, 1886. Ulcers in cæcum and ileum; appendix swollen, and presents two tuberculous ulcers.

Obliteration of the Lumen of the Appendix.—This may be partial or complete, and is more frequent, I think, than the scanty number of cases in my records would indicate. When complete, it may be regarded as advantageous, but obliteration of the cæcal end is a serious danger, as many cases of inflammation and perforation result from the retention of secretion and dilatation. The distended tube may be as thick as the thumb, or even as large as a sausage.

Case I.—Typhoid fever; man, aged 29. Tube of appendix partially obliterated.

Case II.—Typhoid fever; male, aged 40. Appendix obliterated for half an inch of its cæcal end; dilated in the distal part, one inch in length.

Case III.—Male, aged 33; dead of phthisis. The appendix vermiformis obliterated and represented by a firm fibrous cord, one and a half inches in length. There was no special thickening or adhesions in the neighborhood.

Case IV.—Woman; death from a large burn. "Appendix is small, and the lumen completely obliterated."

Foreign Bodies.—I have never met with a foreign body in the appendix; but I was once brought four or five apple pips which had been removed from the tube in a subject in the McGill College dissecting-room, and Dr. William Sutherland, while acting as Pathologist during my absence in 1884, has recorded a case in which six or eight snipe-shot were found in the appendix of a man dead of Bright's disease.

Moulds of fæces are not uncommon, shaped like a date-seed. Sometimes these form concretions and may cause ulceration. It is rather surprising, considering the situation of the appendix, that we do not more often find foreign bodies in it.

Perforation with Perityphlitic Abscess.—*Case I.*—J. B. N., aged 20, admitted October 4, with peritonitis. Notes not available. Death on the 8th. Body well developed. In abdomen, omentum is glued to the anterior wall, and beneath it much creamy pus. The tip of the omentum is closely adherent in the neighborhood of the right internal ring, and here the coils of intestines are matted together. There is general peritonitis and an unusual quantity of thick pus. The ileum, carefully removed and slit open, shows no disease of the mucosa. It contained numerous hard dry fæcal masses. The cæcum looked normal, was placed low, and adhered to the iliac fascia. The mucous membrane was not ulcerated. The appendix passed down toward the internal ring, and adhered closely, covered by the omentum. A probe passed into it enters directly a small abscess near the ring. Slit open, a perforation is seen near the end, on the under side, which leads into the abscess. There was no foreign body.

Case II.—C., male, aged 28, patient of Dr. George Ross, in 1882. Sudden acute pain in right iliac fossa, with great tenderness and high fever. After leeching, the pain subsided, and for several days the condition improved. Then he had a chill, with increased fever. Most careful exploration of the affected region failed to determine any fulness, fluctuation, or signs of localized tumor, and yet it was clear that the patient had a septic process from some acute abdominal affection. Several consultations were held with a view of operation, but the absence of local symptoms determined against it. He had repeated chills, and death occurred from septicæmia. At the autopsy, two quarts of turbid fluid in peritoneum; intestines covered with recent lymph and matted together. The transverse colon was adherent to the ileum, two inches from the valve. About the cæcum the parts looked natural, except at the inner margin, where there was considerable pigmentation. The cæcum itself was normal. On slitting open the appendix, the mucosa for half an inch was healthy; the remainder of the tube was dilated and presented two perforations, the larger of which was the size of a five-cent piece, and communicated with an abscess situated in the angle between the cæcum and ileum, and was partly covered by both these structures. The sac of the abscess, which had the size of a small apple, was closed; had thick dark walls, and contained two ounces of creamy pus. There was an extensive abscess of the mesentery, with suppurative phlebitis of the veins. The portal vein and its branches contained dark greenish-yellow pus. The orifice of the splenic vein was closed with a thrombus.

Case III.—I. L., aged 42. Had typhoid fever, from which he never recovered completely; septic symptoms developed, signs of pleurisy, and finally acute general peritonitis. Duration of illness, three months.

Autopsy. — General peritonitis; eighty ounces of turbid exudation; much lymph on the intestinal coils. The appendix passed out at right angles to the cæcum and lay directly upon the promontory of the sacrum. It had about the length and size of the index finger, and was much swollen and soft. The cæcum was normal; proximal end of appendix closed; a probe passed a couple of lines beneath the mucous membrane, and then met with a firm obstruction. Beyond this the tube of the appendix was dilated, and, when opened, showed a perforation one-third of an inch in diameter, which communicated with a small localized abscess cavity on the promontory of the sacrum. No foreign body; no concretion; extensive abscess of mesentery; liver enlarged; portal vein and branches distended with pus; empyema of left pleura.

Case IV.—J. P., aged 26, patient of Dr. F. W. Campbell. Inflammation of cæcum in July, from which he partially recovered. Recurrence in September: pain in abdomen and local symptoms; then chills and sweats. Death suddenly, October 10.

Autopsy.—Body emaciated. Slight peritonitis. Intestines very dark-colored. Cæcum healthy. Orifice of appendix closed and the tube obliterated for a quarter of an inch; distal portion dilated. On the upper surface, which was covered by peritoneum, there was a localized slough, not extending through the coats. The mucous membrane of the tube was dark-colored and swollen, but not ulcerated. Extensive abscess of mesentery, chiefly in the mesenteric veins. The suppuration extends into the gastric and portal veins, the branches of which on the liver were dilated and full of a creamy greenish-yellow pus.

Case V.—The following case illustrated a most unusual mode of termination, viz., hemorrhage from the bowels:

Male, aged 45. Had a "bilious attack" in February, lasting three weeks. Fourteen months later, another attack—vomiting, flatulence, and constipation; very slight abdominal pains. The motions became offensive, there was irregular fever, and he began to lose flesh. Suddenly, one morning, he passed a large amount of blood in the bed, and the hemorrhage recurred through the day and proved fatal the same evening. The autopsy showed a smooth peritoneum. The lower coils of the ileum were matted together on the promontory of the sacrum, upon which lay a large flat abscess. The cæcum and colon were normal. The appendix passed out at right angles and was attached to the abscess on the sacrum, with which it communicated by two openings at the apex of the tube. There were two perforations from the abscess cavity into the ileum. The hemorrhage had evidently come from this part, but the precise locality could not be determined.

Case VI.—Patient aged 50; was the subject of right inguinal hernia, and on Sunday evening, February 27, was seized suddenly with intense pain in the lower abdominal region. He vomited, and the next day the abdomen was swollen. The pain persisted. On Wednesday he had diarrhœa, and the pain continued to be very severe. On Friday, when admitted to hospital, the belly was tympanitic, vomiting very urgent, and the pain severe. He refused surgical interference, and died on Saturday night. At the autopsy, the cæcum was found adherent to the iliac fascia and passed into the ring, and was attached for at least two inches to the wall of the canal. The ileum was normal, and the finger passed freely through the valve. On searching for the appendix, the proximal orifice was found at the extreme end of the hernia of the cæcum, in the inguinal canal. It then curved upon itself, passed back into the abdomen immediately behind the terminal portion of the ileum, crossed to the left and became adherent to the wall of an abscess cavity lying to the right of the promontory of the sacrum. The lumen of the tube was free; the terminal three-fourths of an inch had sloughed and communicated directly with a small circumscribed abscess-sac with pigmented and indurated walls. This opened into a larger pus-cavity, bounded by the mesentery and ileum in front, and the sigmoid flexure and peritoneum behind.

Perityphlitis from Cæcal Disease.—The following cases of round ulcer of the cæcum are of interest, as the condition is not common:

Case I.—M. G., aged 19, a well-built young man, was in hospital for four days with symptoms of peritonitis; at first it was thought to be obstruction. Three weeks previously he had had an attack of what was supposed to be internal strangulation, from which he recovered.

The autopsy showed recent peritonitis, most intense in the right iliac fossa. There were evidences of bygone peritonitis in the form of opacities and puckering on the serous surfaces. The cæcum was adherent closely to the iliac fascia. When opened *in situ*, an ulcer was seen on the outer wall, and a large perforation over an inch in diameter, leading into a localized abscess in the iliac fossa. The peritonitis had evidently started at this point, though there was no sign of rupture of the abscess. The appendix was normal. It seems probable that in the first illness, three weeks before the fatal attack, the perforation occurred, with the formation of the localized abscess.

Case II.—I. T., aged 38, patient of Dr. Armstrong. Symptoms at first were those of perityphlitis. A septic condition supervened, lasting 15 days; repeated chills. There was dulness in the right lumbar region, due, it was thought, to a tumor of some sort; but on aspiration a clear fluid was obtained.

Autopsy.—Body much emaciated. No tumor or fulness to be felt either in the right iliac fossa or in the lumbar region. In abdomen, intestines very dark-colored; two coils of ileum adherent to the cæcum; two pints of turbid serum in the peritoneum. The cæcum closely adherent by its posterior wall; tissues about it dark, and look thickened. Between the caput cæci and the psoas muscle, lying thus to the inner side of the bowel, was an abscess cavity the size of a small apple, its walls rough, irregular, and shreddy. It contained only a small quantity of a thin sanious pus. The colon and cæcum were opened *in situ*. On the posterior wall of cæcum, was a dark-colored area, in the centre of which was an ulcer the size of a ten-cent piece, which communicated with the abscess cavity by a perforation which would admit a quill. The appendix was unaffected. There was a small ulcer on the lowermost Peyer's patch of the ileum.

Tuberculous and cancerous disease of the cæcum not infrequently lead to perforation and extensive suppuration in contiguous parts, as illustrated by the following case:

Case III.—Middle-aged man. Ill for some months; symptoms of obstruction, and latterly of septic poisoning.

Autopsy.—In abdomen, the cæcum and appendix were seen to be large and distended, and the bowel is constricted just above the entrance of the ileum. The colon and cæcum opened *in situ*. A stricture, with thick hard walls, involved the first two inches of the ascending colon, and just admitted the tip of the little finger; when cut through, the appearance of the mucous surface is that of an open cancerous ulcer. At the posterior wall, this has perforated and communicates with a large abscess by an orifice admitting the index finger. The abscess extends behind the psoas muscle, and has eroded a lateral process of one of the lumbar vertebræ; above, it extends for a short distance behind the kidney; and externally it reaches the crest of the ilium. The appendix was not involved.

CLIMATE AND BRIGHT'S DISEASE.[1]

BY J. C. WILSON, M.D.,

CLINICAL LECTURER ON DISEASES OF THE KIDNEYS AT THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

The relation of climate to Bright's disease is twofold, causative and therapeutic.

All authorities are of accord as to the part played by cold and damp, and especially by sudden cold and damp, in the production of acute nephritis. The causal influence of vicissitudes of weather, and therefore of cold, damp, and changeable climates on the production of the sub-acute and chronic forms of nephritis, is less obvious. Bright's disease is peculiarly an affection of temperate climates, but when we take into consideration the importance properly assigned to modes of life, occupation, diet, alcohol, nervous influences, heredity gout, and lead in its causation, we cannot but be impressed with the long recognized fact that in whichever direction we leave the temperate zone we find a decided and rapid diminution in the frequency of this disease.

Hirsch calls attention to the infrequency of albuminuria in sub-tropical and in extreme northern countries. Dickinson, who has carefully investigated the subject, fully confirms this view from an analysis of the statistics of the British Army Medical Reports for eight years from 1865 to 1872 inclusive. These statistics are of peculiar value, as they represent the frequency of renal affections in bodies of soldiery in every climate and at every season during the same period of time. The observations are drawn from considerable numbers of individuals of the same race, age, occupation, and habits, living under nearly similar conditions, under the

[1] Read before the American Climatological Association, at Washington, D. C., September 20, 1888.

observation of trained observers and with a uniform system of recording facts. They are perhaps vitiated to a certain extent by the effort which has been made to secure accuracy by eliminating from the conclusions the influence of syphilis. Dickinson found that in British America, with its low average and great variability of temperature, renal disorders are nearly as frequent as in the United Kingdom. In Newfoundland, with its exceptionally humid climate, these disorders, so far as regards the limited number of troops there stationed, appear to be even more common than in the British Isles. With the higher temperature of New Zealand, renal disease becomes less frequent, and is least so on the sub-tropical shores and islands of the Mediterranean, and in the solitary out-posts of Mauritius and Bermuda, where a tropical or nearly tropical climate is tempered by a vast circumference of ocean. It is to be noted also that the Cape of Good Hope and St. Helena were comparatively free from renal affections. This accomplished observer also informs us that as the result of an analysis of the published registers of the causes of death, the comparatively cold cities of Great Britain and Australia show a remarkable liability to renal diseases. Paris, though not differing very much in temperature from the more fortunately situated of these cities, has a smaller proportion. Genoa, with its sub-tropical climate, has an almost complete exemption. He found that in the year 1863, in England one death in 106 was due to this cause; in Scotland, one in 109; in Wales, one in 131. Of the several divisions of Scotland, in the mainland rural districts one death in 103, in the towns one death in 112, and in the insular rural districts one death in 188.

The Shetland Islands, with an almost arctic climate, enjoy an immunity from the disease not approached by any other part of the kingdom. It is further noted that within the limits of each kingdom, especially in Scotland, where the climatic differences are much more marked, there is a striking general correspondence between the amount of renal disease and the changeability of the climate. He found that in the Southern hemisphere exposure to a similar climate is attended with the same results. In Melbourne, with a mean temperature of 57°, renal affections are scarcely less common than in London. This appears from the results of general registration, while the mortality from kidney disease in the Melbourne City Hospital, one in thirteen, is much what occurs in similar institutions in England.

On passing the mean of 60° F., the frequency of renal disease displays an extraordinary diminution. "Renal diseases, putting aside that of lardaceous origin, are the compatriot of wheat and barley rather than of the vine and the olive. They abound wherever the climate, however cold during the winter, is warm enough in the summer, as in Canada, to bring wheat to perfection, and become scarce where oranges and lemons grow, and where deciduous trees as generally characteristic of the scenery, are replaced by palms and other tropical endogens. In other words, it prevails wherever the heat for a considerable portion of the year is what would ordinarily be called temperate, whether usually so, as in Great Britain, or so for a large period of the year, as in British North America, where comparatively mild weather divides the year with continuous frost."

Dr. Dickinson's researches further show that with tropical heat, renal disease increases. They also confirm the opinion generally entertained, that the prevalence of these affections is promoted by frequent and abrupt changes. On the western coast of Scotland where there is scarcely heat enough in summer to ripen wheat, but where the winters are warm from the influence of the Gulf Stream, so that a very uniform temperature prevails throughout the year, "renal disease is not half so frequent as on the eastern side of the kingdom, where the weather is both clearer and healthier than on the Atlantic shore, but undergoes much larger and more frequent variations."

The records on which these conclusions are based do not permit of a distinction between the acute inflammatory affections of the kidney and the more insidious and chronic forms of Bright's disease.

I am not aware that similar investigations on a large scale have been made in this country. Without doubt an analysis of the records of the great life insurance companies as regards the proportion of applicants rejected on account of Bright's disease and of deaths due to this cause, would shed much light not only upon the influence of climate, city and rural life, occupation and other important factors in the causation of this disease, but would also yield important facts in regard to the duration of the disease under varying circumstances.

Experience has abundantly proved that climate exerts an influence upon the course and duration of chronic forms of Bright's

disease, scarcely less important than in its causation. The concurrent testimony of all observers who have given their attention to the subject of the climate treatment of Bright's disease, points to the salutary influence of prolonged residence in favorable sub-tropical regions, especially in cases where the disease has not yet made much progress. The late Professor Flint laid great stress upon the importance of a change of climate in chronic Bright's disease. You, yourself, Mr. President,[1] have in your lectures and published writings emphasized it. Tyson and Purdy dwell upon it with a positiveness not found in the earlier writers. Dr. Dickinson goes so far as to say that "the advantage to be expected from a change of sky is at least as great in renal as in pulmonary disease. Cure is a word to be used with caution but I have seen little less, the albumen reduced to a trace, and perhaps that inconstant, and the general health brought up almost to its original level." Dr. George Johnson writes: "Among other remedial agencies, when acute renal disease is prolonged and threatens to become chronic, change of air and scene is often highly beneficial. Residence during the winter season in a warm, dry, equable climate, such as may be found at Cannes, Nice, Mentone and Algiers, has in many instances, been attended with highly beneficial results. The bright warm sun and dry invigorating air favor the action of the skin and of the bronchial mucous membrane; the patient is able to be much in the open air and thus the respiratory, the digestive and the secretory functions are all assisted and promoted. I have seen some most remarkable recoveries effected under the influence of a long voyage after other means had failed to effect a cure."

On the other hand, the climate treatment of Bright's disease seems to have been strangely overlooked by teachers of influence and authority. No reference is made to it in Bartel's article in Ziemssen's Encyclopædia, nor in that of Delafield in Pepper's System, nor in that of Grainger Stewart in Quain's dictionary, recent works of reference on the shelves of practitioners; while in the text-books in the hands of medical students, references to the influence of climate in the causation and treatment of Bright's disease are rare and brief.

The most desirable climates are those which combine the attributes of evenness, dryness, and warmth, with a mean range of temperature between 60° and 65°. On the North American continent, a number of stations in the southern interior meet these indications. Among these are Thomasville and Tallahassee. The stations in the interior and on the Gulf coast of Florida are well suited to this class of patients. Southern California has several suitable stations. Nassau and Bermuda are also to be recommended. The stations on the Mediterranean coast offer especial advantages as winter resorts for patients suffering from chronic Bright's disease, while Algiers, Cairo, and the Cape of Good Hope, are also favorably spoken of.

This paper would have occupied your considerate attention to little purpose, however, had it contained nothing beyond the familiar facts already mentioned. In availing ourselves of the advantages of the climate treatment of Bright's disease, we must not overlook the dangers of abrupt changes of climate and of the vicissitudes of travel in patients in whom the disease has already made some progress. It is with the view of eliciting discussion and obtaining the results of the experience of my colleagues in this Association that I submit certain conclusions drawn from my own experience; and, with the view of saving time, I venture to embody them in the form of the following propositions:

1. The best results of climate treatment in Bright's disease, as in phthisis, are obtained in the early stages of the affection, and by continuous residence. After the general health has become seriously impaired, an amelioration of the symptoms is all that can be hoped for. Alternations of climate, especially those necessitating long and fatiguing journeys by rail are attended with the danger of uræmia.

2. High altitude climates, even when presenting the conditions otherwise favorable, are unsuitable for this class of patients. Uræmic attacks and cardiac failure not infrequently shortly follow change of residence from low to high altitudes—differences of three thousand feet or more.

3. The conditions of North Atlantic steamship travel are often highly unfavorable to those suffering from advanced Bright's disease; especially is severe and prolonged sea-sickness liable, in these cases, to terminate in fatal uræmia.

—At a meeting of physicians and others in Louisville, Ky., called by the Mayor, it was decided to open the gates of Louisville to yellow fever refugees. A train arrived on Sept. 22, with 135 from Decatur.

SOCIETY REPORTS.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

FIRST TRIENNIAL MEETING, AT WASHINGTON, SEPTEMBER 18, 19 AND 20, 1888.

First Session, Tuesday, September 18.

Meeting for Organization.

The meeting was called to order at 1 P.M. by DR. WILLIAM PEPPER, Chairman of the Executive Committe, who spoke as follows:

On behalf of the Executive Committee I have to announce the manner in which we have discharged our responsible duty. The present meeting is the result of prolonged deliberation which began to take shape more than four years ago, before the attention of the medical profession became occupied with preparations of the meeting of the International Medical Congress, but all action was deferred in order that there should not be the semblance of interference with that important meeting. This delay has served to render more conspicuous the necessity for this organization.

In order to produce the best scientific results, it is essential that the numbers in attendance shall be reasonably limited and that as far as possible the same men shall attend successive meetings, securing a continuity of intellectual life and activity. A large proportion of those interested in the development of such an organization are, as I am myself, warmly attached to the American Medical Association, and determined to exert their influence to maintain and promote the success of this great national organization.

Your committee ventures to hope that their provisions will meet the unanimous approval of the Congress. We have recommended that the sessions shall be triennial. We have jealously guarded against the admission of parliamentary business into the Congress, the functions of which are designed to be absolutely and exclusively scientific. We have also guarded the independent sovereingty of each participating society.

Lastly, the Executive Committee has reached the conclusion that the selection of the President of each Congress shall be entrusted to the Executive Committee then in office.

Close study of the conditions of this Congress has led the Committee to feel that if this organization were to have the effect of favoring the multiplication and subdivision of special societies, it would be nothing less than a calamity. We have therefore provided that the admission of new associations shall be secured only by the unanimous vote of the Executive Committee.

It remains only to add that in exerting the privilege of selecting a President for the first Congress of American Physicians and Surgeons, we feel that we have been guided to the choice of a man, whose admirable personal character, whose high attainments, and whose illustrious services in the cause of literature, of science, and of the entire medical profession, mark him as entitled to this great honor and distinction.

It gives us therefore the utmost gratification to present to you our President, Dr. John Shaw Billings, and to announce that the Congress of American Physicians and Surgeons is now duly organized.

President DR. J. S. BILLINGS then took the chair and responded in a brief address.

The

Address of Welcome

was delivered by DR. SAMUEL C. BUSEY of Washington.

The consideration of the By Laws was next taken up.

BY LAWS.

1. This organization shall be known as the Congress of American Physicians and Surgeons.

2. It shall be composed of National Associations for the promotion of medical and allied sciences.

3. It shall hold its sessions triennially in the city of Washington, D. C.

4. The officers of the Congress shall be a President, Vice-Presidents, a Secretary, a Treasurer and an Executive Committee.

5. The President shall be elected by the Executive Committee of which he shall be ex-officio be a member. He shall preside at the sessions of the Congress. He shall deliver an address.

6. The Presidents of the participating societies shall be ex-officio the Vice-Presidents of the Congress.

7. The Secretary and Treasurer shall be elected by the Executive Committee. They shall be ex-officio members of the Executive Committee.

8. The Executive Committee shall be composed of one member from each participating society; and said members shall be elected by the various societies at the next annual meetings subsequent to the Congress.

It shall be charged with all duties pertaining to the organization of and preparation for the ensuing Congress, including the election of all officers and of a Committee of Arrangements.

It shall superintend the publication of the Transactions of the Congress.

9. The expenses of the Congress shall be divided between the participating societies in proportion to their membership.

10. The admission of new associations to participation in the Congress shall be by unanimous vote of the Executive Committee.

These by laws were unanimously adopted. Adjourned.

General Session, Tuesday Evening, Sept. 18.

Dr. Reginald H. Fitz, of Boston, read a paper on

The Medical Relations of Acute Intestinal Obstruction.

The subject of this paper was the diagnosis and medical treatment of the acute internal, mechanical varieties of intestinal obstruction. The only causes recognized were strangulation from adhesions, vitelline remains, peritoneal slits, pockets, and rings; intussusception, twists, and knots; abnormal contents, strictures, and tumors. The evidence presented resulted from an analysis of 295 cases collected from medical literature since 1880.

The most constant symptoms of obstruction were shown to be pain, vomiting, tympany, and tumor. Stoppage of the bowel he did not regard as the most essential symptom in diagnosis, since frequent loose stools characterize intussusception, and may also occur in other varieties of obstruction. Too much attention directed to this symptom, he said, leads to erroneous diagnosis. Stoppage of the bowel is of frequent occurrence in peritonitis, and the opinion that it indicates obstruction often results in irrational and injurious treatment. The physician is called upon to decide whether a given case is one of acute obstruction or not; then to determine its seat and its cause; and finally, to decide what is to be done. The evidence offered by Dr. Fitz showed that the diagnosis is to be made by excluding the various causes of peritonitis. Its seat in the large or small intestine is to be determined by injections, under high pressure, when necessary. The variety is, for most practical purposes, an intussusception; or a twist of the large intestine and strangulation; or gall stones in the small intestine. The differential diagnosis depends on the relative frequency of these varieties, the age of the patient, the antecedent and immediate symptoms.

The treatment consisted, he said, in the attempt to relieve intussusception of the large intestine by forced injection under anæsthesia, combined with the use of massage; and in treating obstructing gall stones with opium, possibly with the aid of laxatives and electricity. All the other varieties of acute obstruction require surgical treatment. The latter treatment is also necessary on or before the third day in cases of intussusception not yielding to forced injections, and in cases of gall stones when the symptoms become urgent.

Dr. N. Senn, of Milwaukee, read a paper on

The Surgical Treatment of Intestinal Obstruction.

Dr. Senn asserted at the very beginning of his paper that all cases of true intestinal obstruction are, in every sense of the word, surgical cases. Intestinal obstruction is present when, from mechanical or dynamic causes, the intestinal canal becomes completely or partly occluded, interfering correspondingly with fecal circulation. It is important that a distinction be made between obstruction due to mechanical causes and that due to dynamic causes. In the former case the surgeon should modify the mechanical cause; in the other, the surgical treatment is limited to diminishing intra-abdominal pressure. Cases of internal intestinal obstruction should be considered in the same light as cases of strangulated hernia. The time that such a case may safely be permitted to go without operation varies. In some, twenty-four hours will suffice for the occurrence of irreparable pathological changes; in others, a much longer time may be allowed to elapse. Operation should be performed as soon as the diagnosis is made.

The surgical resources in the treatment of internal obstruction were taken up seriatim. *Irrigation of the stomach* was first referred to. All forms of intestinal obstruction, no matter what the cause may be, are aggravated by anything that increases the pressure on the proximal side of the obstruction. Irrigation of the stomach relieves this and also diminishes the intra-abdominal pressure. It not only empties the stomach, but also evacuates the contents of a number of feet of the intestine. It will not do, however, to rely upon this as a radical measure, except when the cause of obstruction is of a temporary char-

acter. This measure should always be carried out before a cutting operation, as it prevents vomiting. An antiseptic solution should be used in the irrigation.

Distension of the intestine. The mechanical effects of this measure—distension with a fluid—he said, are limited to the colon. The fluid does not pass beyond the ileo-cæcal valve. Why should we not, in these cases, resort to the lightest possible substance known—hydrogen gas—which is harmless, readily obtained, and aseptic? A pressure of from one-fourth to two pounds to the square inch overcomes the resistance of the ileo-cæcal valve, and forces the gas from the anus to the mouth. A pressure of eight to ten pounds to the square inch is required to produce palpable injury to any of the coats of the intestine. If perforation takes place there is at once a positive indication for opening the abdomen. The fact that perforation has occurred is shown by the disappearance of the liver dulness.

Manual exploration by the rectum is a useful diagnostic and therapeutic measure when the obstruction is below the sigmoid flexure, provided the surgeon has a small hand.

Taxis and massage should be limited to cases in which the obstruction is due to intra-mural causes, and to a few cases of invagination. Uniform, uninterrupted equable *pressure of the abdomen* is useful in preventing hyper-distension in these cases, especially where dynamic causes are feared.

Enterotomy, so frequently practiced in the past, he said he hoped had become very nearly obsolete. It should be employed only where it is clear that the patient will not be able to pass through the ordeal of laparotomy.

Lumbar colotomy. In cases in which this operation was formerly employed, we can often avoid the necessity for colotomy by uniting the portion of bowel above the obstruction with that below by means of decalcified bone plates. Dr. Senn said he had specimens showing that a dilated congested bowel can be repaired when excluded from the fecal circulation in this way.

He also said he had, in the past eight months, performed gastro-enterostomy in four cases by this method. In all of these cases the operation was a success, although in one case the patient died because the operation had been postponed too long. In one case the advice of Leucke had been followed, and the first presenting portion of the bowel had been fastened to the stomach. The patient continued in good condition for nine days, when symptoms of obstruction came on, and he died in three weeks. It was found that the connection with the bowel was eight feet below the pyloric orifice, and that the movements of the bowel had produced a sharp flexion of the intestine, causing obstruction. Gastro-enterostomy in incurable carcinoma is a safe operation, and one which the surgeon owes to all such patients.

In opening the discussion, Dr. Arthur Durham, of London, said that he had taken much interest in this subject. There is no class of cases which is more serious or more dangerous than that of intestinal obstruction. He agrees with Dr. Senn, that usually the sooner the surgeon is called in these cases the better. As soon as the diagnosis is made, the operation should be performed. In some cases it should be done before a positive diagnosis is reached, and in order to clear up the diagnosis. Under such circumstances, the surgeon must be prepared to meet the indications that present themselves. In trying to reach a diagnosis, the probabilities in favor of this or that condition, based upon statistics, should not influence us; but the case should be studied on its own merits, and treated as its indications may demand. In regard to the injection of hydrogen gas, Dr. Durham suggested the possibility of the formation of explosive compounds, and thought that atmospheric air might be substituted.

In cases of acute obstruction in which there is reason to believe that the cause is in the small intestine, provided the symptoms are severe and urgent, the proper thing, even if an absolute diagnosis has not been made, is to open the abdomen and search for the cause, and relieve it in the best way possible. On the other hand, when the cause is in the large rather than the small intestine, there is not the same degree of urgency. He strongly advocated lumbar colotomy in certain cases. In some cases, after colotomy, there has been a gradual restoration of the bowel, and the patient has recovered completely

Dr. William Ord, of London, admitted that there was often a great deal of difficulty in the diagnosis He was in favor of the views of Dr. Fitz, and claimed a little time before resorting to operation. In some of these cases, under the use of hypnotics and time, the cause of obstruction had disappeared. Where, however, there is mechanical obstruction the case must, sooner or later, go into the hands of the surgeon. This time, he said, should be a

short one. The operation is a serious one, especially in people over fifty years of age. He said he had seen the operation performed often, and frequently fail in those cases in which there was the most reason to look for success.

Mr. Thomas Annandale, of Edinburgh, said: These cases of obstruction should be divided into two classes, the acute and the chronic. In acute cases medical measures should be tried, but not continued too long. If the symptoms are urgent, the surgeon should be called at the end of forty-eight hours. The sooner the abdomen is opened, the better. In the chronic cases, we may wait a considerable time, even until the symptoms become acute. The treatment should then be that applicable to a case of acute obstruction. He had largely given up lumbar colotomy, which he had employed more especially in rectal obstruction, and resorts to inguinal colotomy as a simpler and not more serious operation in most cases.

Dr. N. Senn, in closing the discussion, stated that there was not the least danger in the use of hydrogen gas. He had performed many experiments on animals, and had used the procedure in man. In cases of intestinal perforation, it aids the diagnosis and allows the surgeon to determine whether or not all the openings have been closed. In a recent case of gunshot wound, eleven openings near the ileo-cæcal valve were closed, and a twelfth was revealed by the hydrogen gas at the point at which the peritoneum is reflected from the bowel to the bladder. The patient is doing well, one week after the operation.

Dr. Charles K. Mills, of Philadelphia, read a paper on

Cerebral Localization in its Practical Relations.

In his introductory remarks, the speaker referred to the fact that from the clinical observation of practical physicians sprang the conceptions out of which developed the science and art of cerebral localization. Allusion was made to the discoveries of Bouillaud and of Broca on speech localization; to the announcement by J. Hughlings Jackson in 1864, that certain convolutions superintended the delicate movements of the hand which were under the immediate control of the mind, and to the fact that Hitzig's researches had originated from his observing certain movements of the eyes during galvanization of the heads of his patients. Brief reference was made to the history of American work in cerebral localization; to the investigations in 1874 of the New York Society of Neurology and Electrology; to Putnam's discovery that irritation of the white matter beneath definite cortical centres produced movements similar to those caused by irritation of the centres themselves; to the labors of Wood and Ott on the heat centres, and to the light thrown by these investigations upon the mechanism of fever and the action of drugs upon different forms of high temperature.

Before taking up the surgical aspects of the question, the speaker briefly discussed some of the practical results wrought by cerebral localization for psychological medicine and medical jurisprudence, for general symptomatology and diagnosis, and for medical therapeutics and technique. Trephining for insanity, especially when guided by the rules of localization, was briefly considered. Two of the recent cases of brain operation reported by Bennett and Gould, and by Macewen, were cited as possibly opening a new field for surgical interference in insanity—the excision of cortical areas as a method of treatment when certain subjective phenomena, such as hallucinations of sight or hearing, can be given a local habitation in the brain.

Turning to the surgical aspect of cerebral localization in its practical relations, he discussed first the forms of disease and injury in which cerebral localization is a valuable aid to diagnosis; second, the topographical diagnosis of the parts of the brain accessible to surgical interference, and some sources of error in such diagnosis. The forms of disease in which such diagnosis has been used, are intracranial tumors, cysts, fractures, hemorrhages, abscesses, and discharging cortical areas.

In considering the localization of brain tumors, Dr. Mills referred to twenty cases of autopsies occurring in his own personal experience, in about one-half of which the tumors were in surgically accessible areas, and in at least one-fourth of which successful operations might have been performed. From this experience, he advocated the excision of old gummata, and also, in special cases, of tubercular growths. The value of localization was shown in cases of fracture when the extent of the unseen damage could not be told by the position and character of the visible lesions.

Of the different forms of intra-cranial hemorrhage, the sub-dural, cortical and intra-cerebral are most amenable to topo-

graphical diagnosis. The rules for the local diagnosis of these forms of hemorrhage were then given. Dr. Mills advocated the performance of trephining in exceptional cases of hemorrhage into the ganglia and capsules—cases in which the symptoms indicated that the bleeding had not broken into and inundated the ventricles. The best site for operation in such cases is in the anterior portion of the first or second temporal gyrus. He favored Hughlings Jackson's suggestion of excising localized cortical areas, even when coarse lesions could not be made out, in cases of spasm, beginning locally or deliberately. The inaccessible areas had been narrowed down by venturesome surgical explorers, and had become reduced to the middle regions of the base and its bordering convolutions, the corpora quadrigemina, the pons and the medulla oblongata.

The characteristics of localizing symptoms were described as phenomena of irritation, destruction, instability, pressure, invasion, and reflex action. Signal symptoms and the serial order of motor phenomena were discussed. In certain regions of the brain an accurate topographical diagnosis can be made with great certainty from positive localizing symptoms. These brain areas include the entire motor zone, in which are embraced the motor or emissive speech area, the region of Broca, the visual area in the cuneus, giving lateral hemianopsia, and the intra-cerebral visual tracts; possibly also the angular gyre and the lateral surface of the occipital lobe. In other regions of the encephalon, the topographical diagnosis could be made with sufficient accuracy for surgical purposes by the study of the positive symptoms, with, in addition, the application of processes of exclusion and successive differentiation. Special stress was laid upon the importance of pressure and invasion symptoms. These areas for approximately certain topographical diagnosis, include the cerebellum, the pre-frontal lobe, the temporal lobe, and even certain cranial nerve-districts, as the auditory and facial, when the lesion could be localized within the cranium between the superficial origin of the nerves and their entrance into their foramina or canals of exit. Motor localization had become almost an exact science. The latest physiological research bearing upon the subdivision of the motor area and the light thrown upon the question by surgical operations were discussed. It was held to be imperative for the neurologist and surgeon to have exact knowledge, not only of the anterior and the posterior limits, but also of horizontal sub-divisions of the motor zone. The old method of sub-dividing the motor zone into three elliptical or circular areas from above downward was considered insufficient; but the neurologist should be able to locate for the surgeon from a study of motor phenomena at least seven or eight positions for trephining; these positions being selected by a close study of the initial or signal symptoms, the serial order of movements, and also of the amount and character of the temporary paralysis after the seizure and the method of extension of the persisting palsy. Reference was made to operations performed through accurate localization in these areas.

The neurologist and surgeon must depend upon motor symptoms alone in fixing the site for operation in cases in which the motor lesions were definite. When positive sensory symptoms were present, they might sometimes serve to aid in locating more exactly the position for operation, but the data were not sufficient for positive reliance.

The question of morphological peculiarities of the human brain was briefly alluded to as having some practical bearing upon the subject under discussion. The position of the so-called angular gyre and aberrations in the parieto-occipital region were more particularly discussed. Even the fissure of Sylvius, the central and parieto-occipital fissures sometimes present considerable variation; but, as a rule, such aberrations were not confusing in operating on the motor region.

Dr. Roswell Park, of Buffalo, N. Y., read a paper on

Cerebral Localization in its Surgical Relations.

This essay was devoted purely to the surgical aspects of the subject, and omitted consideration of those cases in which operation is dictated by a study of the subjective rather than of the objective features.

Cerebral Topographical Anatomy. The areas which most concern the surgeon are those which surround the fissure of Rolando. Lesions of the dura-mater overlying motor areas are not always to be distinguished from lesions in the cortex beneath. It is enough for the surgeon that a lesion of some kind can be located with reasonable accuracy. It matters not whether this is an old irritative lesion, an acute suppurative process between the bone and the brain, or an abscess or tumor of the brain itself. The indication for exploration is just as strong in either case.

Where can one trephine with safety? The safest rule is to first apply the trephine over those areas which do not overlie large vascular channels. Afterward the opening may be extended in any direction and to any required extent. The greatest hesitation is with regard to opening one of the sinuses. Two dangers attend such an accident: one, fatal air embolism; the other, profuse hemorrhage. The former danger is almost a theoretical one, and the other may be overcome by plugging the sinus or closing its wound with a fine needle and suture.

Cerebral and Cerebellar Abscess. Bergmann has shown that abscess of the brain has but one result: death; and that the surgeon's knife offers the only relief. So far as we know, there is no such thing as idiopathic abscess of the brain; it is always the result of some external wound of the head, or some extension from diseased bone. The only exceptions to this statement are to be found in the case of pyæmia or tuberculous abscess. The symptoms of deep brain abscess may be divided into three groups: 1. Those which are plainly due to suppuration. 2. Those of increased intra-cranial pressure and of disturbed relations. 3. Special symptoms by which the locality of the disturbance may be ascertained. So long as the gray matter is undestroyed, the collection of pus may assume large dimensions, and still no intense motor symptoms appear. Local elevation of temperature over the abscess is a symptom of importance when present, but its absence does not negative a diagnosis made on other grounds. Wernicke has stated that there is a peculiar disturbance of speech which points to lesion of the temporal region. This is the confusion of correct with incorrect words. In the general diagnosis of cerebral abscess, it is to be remembered that there usually is a latent period, which may continue for an indefinite period. The stage of active symptoms is usually ushered in by more or less headache; slight rise in temperature; local or motor symptoms can only be expected when the abscess is in the motor area of the brain.

Operation for Abscess of the Brain. Until recently operators have satisfied themselves with incising the dura. With the introduction of aspirating methods, the hollow needle came to be used for brain exploration. The dangers of this procedure are certainly small. The danger of hemorrhage has been over-estimated. A temporary tampon will control deep hemorrhage, while bleeding from the vessels of the pia-mater may be controlled with ligatures or *serres fines*.

Brain Tumors.—Considered in their surgical relations these may be divided into (1) the circumscribed or encapsulated, and (2) the infiltrated or diffuse, around which as a rule, there is a zone of softening; and a third class may be mentioned, *i. e.*, those growing from the interior of the cranium, from the bone or dura.

White found in the dead room of Guy's hospital, one hundred brain tumors, of which only nine could have been removed—one tuberculous nodule, four sarcomas, two undetermined tumors, one cyst and one myxoma.

Operation for Intracranial Tumors. The head should be shaved two or three days before operation, washed with green soap and ether, and antiseptic compresses applied. Chloroform should be, as a rule, the anæsthetic, on account of its contracting influence on the vessels of the brain. Morphia hypodermically and ergot may be resorted to for the same purpose. The author suggested that after localizing the lesion, a small, disinfected, headless tack be driven through the scalp into the bone at the point determined upon. After the dissection of the external flap, this will point out accurately the point to be first attacked. In order to prevent hemorrhage, the author had found a spray of antipyrine solution (1 to 40) of service. The semilunar flap is the proper one to raise. Its apex should be in such a position as to allow of drainage with the patient on his back. The periosteum should preferably be raised with the flap. The use of the trephine is preferable to the hammer and chisel. Since Macewen has taught us how to preserve the fragments of bone and restore them to their place, his method has been widely tried and universally commended. The dura mater should be incised around a large part of the area at a distance of $\frac{1}{8}$ to $\frac{1}{4}$ inch from the edge of the bone. The appearance of the dura is sometimes a guide to trouble beneath. In recent cases, it is sometimes highly vascular; in old cases, it may be yellowish or discolored. Wherever adherent it should be freely excised. Horsley asserts that marked protrusion of the dura indicates pathological intra-cranial tension. The color of the brain should be noted, remembering that the cerebellum has normally a different appearance from the cerebrum. Sometimes, where there is uncertainty as to which convolution is the desired one, the battery may be employed. Where no indication of lesion

is found, further exploration may be conducted with a small aspirating needle or a blunt probe.

Should a tumor be discovered, the incisions for its removal should be made perpendicularly to the cortex, for the purpose of avoiding hemorrhage and division of the conducting fibres. Removal of a layer of cortex, whether normal or abnormal, does not leave, as one might fear, a prominent gap with vertical sides, since in a short time the depressed portion is made to bulge almost to the level of the intact surrounding parts. In addition, the cut edges are also slightly everted, and if less brain is removed than bone, the edges are extruded into the opening in the skull; thus there is a continual normal tendency to hernia; but Bergmann and others have shown that this tendency to hernia-cerebri is in inverse ratio to the area of bone removed. Experience has taught that it is wise to remove brain tissue to an extent greater than was at first considered justifiable. In all operations for epilepsy the portions of cortex nearest the evident lesion should be freely removed.

The matter of drainage must be determined according to the circumstances of the case. An abscess must be drained as long as pus is discharged. After the antiseptic removal of a tumor, the cavity should seldom be drained for more than twenty-four hours. The provision for drainage may be removed on the second day, and the wound dressed with reasonable pressure over the flap. Exudation naturally collecting in this cavity, will be retained and will give rise to some pain and disturbance; but so long as the symptoms from this are not severe, the wound may be left with confidence that the fluid will be reabsorbed and that the pressure will be the best check to protrusion.

Dangers of the Operation. The principal immediate dangers are two:—hemorrhage and œdema. Hemorrhage from the pia or from the brain substance is usually readily controlled, but disastrous hemorrhage may occur from unexpected sources. When there is bleeding, a temporary tampon of iodoform gauze may be applied. The dural and skin flaps are laid over this and an absorbent dressing applied. At the end of forty-eight hours this may be removed and sutures inserted.

The second danger, that of acute brain œdema, may be brought about either by increase of intra-arterial pressure or by obstruction of the venous channels of escape. Under this accumulation, the brain becomes more sodden. Removal of a portion of the cranium is virtually a diminution of the pressure normally exercised on its contents and is often followed by reaction with production of excess of fluid.

Dr. Park said he had collected reports of 63 cases, which were presented in summary and in tabular form. Of these cases seventeen terminated fatally, although only five of these deaths could properly be attributed to the operation. Fifteen of the cases were abscesses, sub-dural or sub-cortical. In eleven cases the lesion was a tumor, exclusive of tubercular nodules. Of cysts, properly speaking, there were 12. The 25 other cases were of a miscellaneous nature. In three cases, the true character of the lesion was not revealed during the operation, and was only discovered at the autopsy. In two cases, in which no palpable or visible lesion was discovered at the time of operating, the symptoms which led to the performance of the operation were nevertheless relieved, though nothing but careful exploration was practiced.

Of the 63 operations, 17 were performed by American surgeons. Those who have themselves operated more than once are, with the number of their operations: Macewen, 12; Horsley, 11; Bergmann, 4; Weir, 3; Keen, 3; and Park, 3.

Third Session, Wednesday Evening, Sept. 19.

Dr. David Ferier, of London, in opening the discussion on the papers of Dr. Mills and Dr. Park, said that he took special pride and satisfaction in the fact that this subject had been assigned such an important place in this great gathering of the profession in this country. He had long cherished the idea that the determination of the functions of the brain would in time lead to the successful treatment by surgery of some of the most distressing ailments of our fellow creatures. When he first broached the possibility of this he received little encouragement, but now cerebral surgery had become a distinct branch of the art of surgery. There is a great future for cerebral surgery. We must, however, be cautious lest we do things which our better judgment and larger experience may not consider altogether justifiable. While there have been many successes, yet there had been some failures. He alluded more especially to cases of Jacksonian epilepsy. The discharging lesion has been removed in many of these cases without permanent cure. Care must also be taken

that in curing one affection we do not induce a greater evil. There is yet much to be learned in regard to the functions of the brain and in regard to the diagnosis of cerebral disease.

Mr. Victor Horsley, of London, described briefly the results of his experiments upon the motor region. He believed that here three functions were clearly represented: 1, the representation of the so-called tactile sense; 2, representation of the so-called motor sense; and 3, the great representation of movement. It is found that morphologically the large cells in the fourth layer are concerned in the representation of movement, and he could not understand why we should not allot to the small cells in the upper layer the representation of sensation. He had divided the motor region into minute areas and studied the effect of irritation of these separate areas. He had found that the representation for any part was not limited to one minute portion of the brain, but that there was a focal point where it was strongest and then it gradually diminished as we passed outward. In his different experiments he had met with certain points of difference. These were attributable to the employment of different species of monkeys. He now uses only the bonnet monkey, and for all practical surgical purposes the results are perfectly applicable to man.

Experiments performed during the past summer had enabled him to prove that the convulsions of so-called Jacksonian epilepsy were solely due to the cortex, and not at all dependent upon the spinal cord or upon the bulbar spinal system.

In cerebral surgery we practice simply the ordinary rules of surgery. In cutting out the bone, a one-inch trephine should be first used to determine the thickness of the skull. The surgical engine may then be used to cut almost through the portion of bone to be removed. The bone may then be removed with strong forceps. The dura-mater should be first separated. If nothing is found and the operation is an exploratory one, the dura-mater should be opened. If we propose to use Faradism for the recognition of certain areas, it is important that the ordinary antiseptic solutions should not be applied to the brain, for they tend to prevent the response to the electric current.

Parenchymatous hemorrhage may be prevented by the use of morphia. The ligature must be always applied if possible. Never pack the wound. In regard to the recurrence of epilepsy in operations performed for the relief of this affection, he considered that the recurrence was due to incomplete operation. In those cases in which he had removed to his own satisfaction not only the lesion but the surrounding brain substance for at least one centimetre, there had been no return.

He agreed with the previous speaker that there was danger of doing too much in certain cases.

Dr. M. Allen Starr, of New York, read a paper on

Cerebral Localization in Reference to Aphasia.

It is evident from the statements just made that cerebral surgery has a great future but is dependent on neurology for its guide. The burden of responsibility for future progress rests upon physicians, for diagnosis must precede operation. The great discoveries in cerebral localization, made in the past, have been reached by means of the collection and analysis of large numbers of cases of localized disease in man, rather than through physiological experiment. Future advance must be in the same line. Hence the importance, too much overlooked in this country, of recording carefully every case of cerebral disease. And to be properly recorded it must be carefully examined. This is especially necessary in the cases of disturbances of speech.

The history of aphasia presents three epochs: First, that of Broca, in which the fact was established that lesions of the third frontal convolution on the left hemisphere produced aphasia; secondly, that of Wernicke, in which a distinction between sensory and motor aphasia was drawn and the former was shown in a few cases to be due to lesion of the first temporal convolution; thirdly, that of Charcot, in which the four mental elements of speech were carefully separated. Charcot says: "a word is a complexus; in it we can discover, in persons of education, four distinct elements; the auditory memory picture by whose means we are able to grasp the sense of words heard; the visual memory picture which enables us to comprehend the words written or printed; and also two motor elements, the motor memory of articulation and the motor memory of writing—the first developed by the repetition of movements of the tongue and lips necessary to pronounce a word; the second by the practice of motions of the hand and fingers necessary for writing." Each of these memories being distinct can be lost. The result is disturbance of speech whose forms vary. The loss of visual memories produces verbal

amnesia and word blindness; the loss of auditory memories causes word deafness; the loss of motor memories of writing results in agraphia; the loss of motor memories of pronunciation produces motor aphasia. Individuals differ largely in the degree of cultivation of each of these memories, and hence suffer differently when affected by their loss, *e. g.*, the literary man presenting far more symptoms than a common laborer, when his memories of things read are lost. Another fact of importance is the independence of speech and thought. Aphasics may retain their musical faculties and may sing when they can not talk. Thinking, though largely done by the aid of speech, is not dependent upon it. We have memory pictures of the shape, form, sound and odor of objects independent of their names; and unless these are intact in the brain, the perception of the object does not produce recognition of its nature or use, and does not awaken the memory of its name. The condition termed apoaxia, is found with aphasia in some cases, but not in all.

Turning from clinical distinctions to pathology, the localization of the various memories necessary to speech, was discussed. Motor aphasia is produced by lesion in Broca's centre, or in the tract from that centre to the cranial nerve nuclei. If it is due to lesion in the latter, it is temporary and accompanied by other local symptoms. The situation of the lesion producing motor agraphia is uncertain. Word deafness is due to lesion in the first temporal convolution and is associated with word blindness when the lesion extends to the supra marginal convolution and angular gyrus. All the cases of pure sensory aphasia in which the lesion was limited to these parts (41 in number) were collected and a chart of the brain was shown to support the localization stated. The condition of apoaxia was shown to accompany lesions situated in or beneath the angular gyrus.

The integrity of the connecting tracts between the various memory-centres is also necessary to the act of speech. These can be tested; thus repetition after another, copying, writing at dictation and reading aloud, are acts involving two separate areas and their connecting tract. Lesions of these tracts produce disturbances of speech, some of which Lichtheim has described. But cases have not yet been sufficiently well tested to warrant any conclusions. The necessity of careful examination of all cases to detect various defects was dwelt upon, and the speaker closed by indicating how readily accessible to surgical interference the speech areas of the brain are.

Dr. W. W. Keen, of Philadelphia, compared the head cavity to the other cavities of the body. The brain may be considered to be made up of a number of viscera having separate and distinct functions, and each of which has its own physical signs and symptoms. While we should be careful not to do too much, we should not err in the other direction. The timidity with which the surgeon formerly approached the abdominal cavity was remarkable; the boldness with which we now attack the lesions of this cavity is almost appalling and the success equally gratifying. This history will be repeated in the case of the brain.

Dr. Robert F. Weir, of New York, had since 1883 operated in 10 cases of brain disorder: three times for tumor; three for abscess; twice for hemorrhage into the cerebrum where there was no external injury to indicate its locality; once for epilepsy, and once for cerebral pain. In the last case the tumor was so deep that there was nothing to indicate its presence after the brain was exposed. It was one and a half inches below the surface. The growth proved to be a sarcoma. The operation was done last November. The patient is still living, but there are signs of a recurrence of the growth.

Bergman says that operation should not be performed when the patient is in coma or where the tumor is large. Dr. Keen has removed a tumor weighing over four ounces, with recovery, and Mr. Horsley has removed with success a tumor weighing four and a half ounces from a patient in a state of coma. Sometimes, although no tumor is found, the operation causes disappearance of the symptoms by relieving the pressure. This might be applicable in apoplectic hemorrhage where the clot could not be removed.

I have gone over the brain to find what parts are accessible to surgical interference. We are able to strip up the longitudinal and lateral sinuses to a considerable extent. The dura-mater may be separated for a considerable distance from the bone. He had been able to raise up the frontal lobe so as to see the anterior clinoid processes, and he had been able to feel the foramen magnum.

ADJOURNED.

Thursday evening's session was devoted to the Address of the President, Dr. J. S. Billings, on Medical Museums.

AMERICAN RHINOLOGICAL ASSOCIATION.

SIXTH ANNUAL MEETING, AT CINCINNATI, OHIO, SEPT. 12, 13, AND 14.

First Day—Wednesday, September 12.

The Association met at the Gibson House, and was called to order at 10.00 A. M., by the President, Dr. C. H. Von Klein, of Dayton, O.

Dr. A. B. Thrasher, of Cincinnati, delivered an Address of Welcome, after which the President, in his annual remarks, dwelt upon the progress of rhinology.

Dr. J. E. Schadle, of St. Paul, read a paper on

Chorea of the Soft Palate

caused by the hypertrophy and hyperæsthesia of the mucous membrane covering both inferior turbinated bodies. He said some forms of headache and of spasmodic asthma are in many instances the outgrowth of a nasal polypus, a thickening of the turbinated bodies, or a septal deformity. These reflex neurotic disturbances disappear after appropriate measures of treatment have been directed toward the removal of their cause.

The patient was examined by Dr. Schadle on April 16, 1888. She then suffered from constipation and flatulency quite frequently. The heart's action was more or less excited, the heart beating tumultuously when she ascended a flight of stairs, a hill, or some other elevation. She complained of marked obstructed nose-breathing; voice was impaired, especially when singing. The principal difficulty for which she was sent to him was the spasmodic movement of the velum palati. A faucial examination revealed distinct rhythmical choreiform movements of the velum palati, accompanied by a peculiar clicking sound, distinctly audible for a distance of twelve or fifteen feet from the patient. Anterior rhinoscopic examination revealed chronic hypertrophy of the inferior turbinate bones, more especially the middle one, whose redundant tissue caused pressure on the septum and so produced obstruction of the middle meatus. The treatment was mainly surgical. Snaring was impracticable. By the use of Cohen's post-nasal cutting forceps and the electro-cautery, he reduced the growth entirely, the procedure being followed by cessation of the choreiform movements.

At the Afternoon Session, Dr. Thos. F. Rumbold, of St. Louis, Mo., read a paper on

The Etiology and Pathology of Nasal Diseases,

in which he said that the etiology of a disease is of the greatest import, and a perfect understanding of its causes and its mechanism the goal of the pathologist. As regards heredity in the causation of rhinitis, he said he had long been convinced that such a theory is erroneous. The histological facts concerning cell-life in his opinion prove a successful contradiction of the theory of heredity.

Second Day—Thursday, September 13.

Dr. John North, of Keokuk, Iowa, read a paper entitled

The Relation of Nasal Diseases to Other Affections, Including the Brain and Nervous System.

There is no organ, he said, in the entire body which has been so neglected as the nose. Obscure and obstinate diseases have not yielded to treatment because the latter has been directed to the effect of nasal reflex troubles and not to the nose, the cause of the trouble. In 1886, Dr. North sought to prove that neurasthenia is frequently the result of chronic naso-pharyngeal catarrh; he reported to substantiate his argument several cases, in which the neurasthenia had yielded to treatment applied to the naso-pharynx.

Dr. Thomas F. Rumbold read a paper on

The Effect of Nasal Inflammation on the Mind,

in which he argued that a normal condition of the mind depends upon a normal supply of blood to the normal brain; and that, if an acute inflammation in the nasal passages is accompanied by mental manifestations, mental incapacity of a more severe character must accompany a chronic rhinitis.

Dr. Rumbold's paper was followed by one on

The Etiology and Pathology of Acute Catarrh,

by Dr. J. G. Carpenter, of Standford, Kentucky.

Among the most prominent causes of acute catarrh, he mentioned occupations which exposed a person to an atmosphere full of dust, smoke, or excessive moisture—or to a dry and dusty atmosphere. Other causes that he mentioned are going about

insufficiently clad, the evil results of ordinary slippers, etc.

Pathologically, he said, acute catarrh is divided into three stages: 1. The dry stage, attended with hyperæmia, redness, heat, tumefaction, and pain in the mucous membrane, which presented a red, dry, or dark-red appearance. 2. The moist stage, supplementing the first, in which there is transudation of serum, diapedesis of the white corpuscles into the connective tissue, cell proliferation, and organization of lymph. 3. The presence of pathological conditions with denudation of the epithelium, and the presence of a raw surface; the excessive mucous secretion is changed to a muco-purulent or purulent one.

At the Afternoon Session, Dr. R. S. Knode, of Fort Wayne, Ind., read a paper on

Intra-Nasal Obstruction,

in the course of which he said that of all the mucous surfaces, that of the nose is perhaps the most sensitive to irritating gases, vapors, and dusts of different kinds, as well as to sudden changes of the atmosphere. Intra-nasal obstructions may be temporary or permanent, partial or complete, owing to the extent of inflammation or injury that produces them. Temporary occlusion is usually the result of some one of the forms of acute rhinitis. From severe attacks, or from the effects of repeated colds, the membrane may be found overwhelmed with plastic material, with a loss of nerve power, a pale, flabby, wrinkled condition somewhat resembling polypus, but more sensitive to the touch, and completely filling up both cavities of the nose. In this condition, he said he had found nothing to act so promptly as an application of a one per cent. solution of cocaine, applied with a probe and cotton, and followed with mildly stimulating solutions of chromic acid, ten grains to a fluid ounce, after which the vaseline treatment should be used. If stenosis should return, a second application of the acid may be made, or slippery-elm plugs slightly moistened with a weak preparation of cocaine and Listerine may be used instead.

Dr. E. G. Kegley, of Cedar Rapids, Iowa, reported a case of

Enlarged Tonsils with Peculiar Symptoms,

relieved by the galvano-cautery snare. The patient was a man forty-three years of age, who first consulted him in January, 1888, with regard to a trouble which the patient termed "drueling." He presented the appearances of one suffering with hay fever. His eyes were red and swollen, with excessive lachrymation; there was continual flowing from the nose, with the addition of a constant spitting of clear fluid. Examination revealed the nasal mucous membrane highly congested and completely closing the nasal passages. The patient's mouth was continually filled with saliva, and the tonsils enormously enlarged, filling the back part of the mouth and throat. Dr. Kegley applied cocaine to the tonsils and removed them both at one sitting by means of the galvano-cautery snare, the patient having experienced no pain whatever. He saw the patient the next day, and learned that the trouble had ceased almost simultaneously with the removal of the tonsils. There has been no further trouble.

Third Day—Friday, September 14.

Dr. A. G. Hobbs, of Atlanta, Ga., read a paper on the

Surgery of Gummatous Growths of the Nasal Cavities,

and reported four cases. In the first case he sprayed the nasal passages with a five per cent. solution of cocaine, and then attempted to introduce a Blake's snare, but found it impossible to engage the tumor in the loop. He therefore introduced a cutting spoon and several large masses of the growth were cut away. Four more sittings at intervals of three days enabled him to remove the growth entirely. The patient has since completely regained her health.

At the Afternoon Session Dr. A. B. Thrasher read a paper on

The Surgical Treatment of Nasal Catarrh,

in which he said that there are forms of nasal catarrh which can only be benefited, and not cured, by medicinal treatment. When there are mechanical obstructions to the lumen of the naris of a hypertrophic, hyperplastic, or neoplastic character, surgery offers the most direct path for the removal of the difficulty. With regard to the best method of procedure, he said that there are some cases in which the application of a chemical caustic answers the purpose admirably. The Woakes' gauge or plow will do the work, and by the aid of cocaine will do it rapidly and painlessly.

In uncomplicated cases of chronic hypertrophic rhinitis, the conditions to be met are: (1) Obstructions to the lumen of the naris, and (2) abnormal condition of the

mucous glands. The causal indications would at once suggest a removal of the redundant tissue. The means employed should look to the accomplishment of this end and with the least resulting scar surface, so that the natural condition of the epithelial covering might be as nearly as possible simulated. To reach this result he had met with the most marked success in the use of the galvano-cautery knife. He first anæsthetizes the part with cocaine, then introduces the knife to the posterior part of the hypertrophy, turns the sharp edge toward the tissue to be cut, heats the knife white hot, and cuts deeply, drawing the knife forward. The result is a deep linear scar in an antero-posterior direction through the hypertrophic tissue. He cuts deeply enough to destroy a portion of the submucous erectile tissue.

The following officers were elected to serve for 1889:

President, Dr. John North, Keokuk, Iowa; *First Vice-President*, Dr. A. G. Hobbs, Atlanta, Ga.; *Second Vice-President*, Dr. A. B. Thrasher, Cincinnati, O.; *Secretary and Treasurer*, Dr. R. S. Knode, Fort Wayne, Ind.; *Librarian*, Dr. N. R. Gordon, Springfield, Ill.; *Members of Council*, Dr. Hiram Christopher, St. Joseph, Mo., Dr. J. G. Carpenter, Standford, Ky., Dr. Thomas F. Rumbold, St. Louis, Mo., and Dr. J. G. Sinclair.

Next place of meeting, Chicago, in September.

PERISCOPE.

Corrosive Sublimate Poisoning in Lying-in Women.

At the meeting of the Obstetrical Society of London, July 4, 1888, Dr. Robert Boxall read a paper on the Conditions which favor Mercurialism in Lying-in Women, with Suggestions for its Prevention. The question was debated under two separate headings: (1) Increased absorption (2) defective elimination. Under the first head the site of absorption was discussed; the question as to whether or not the solution obtains entrance to the cavity of the uterus when the uterine tube has not been employed was debated, and an experimental investigation undertaken with a view to determine the point was related. It was suggested that absorption not infrequently occurs inside the uterus, even when the uterine tube has not been employed, but that it may also take place through the lacerated surfaces of the cervix, vagina, and perineum, or even through the intact mucous membrane. Reference was made to the experimental research conducted by MM. Doléris and L. Butte, which bears on this point. With a view to diminish the risk of absorption, it was suggested (1) that not only should care be exercised to obtain contraction of the uterus, but that contraction should also be carefully maintained, and, above all, that the douche should always be given at such a temperature as will stimulate the uterus to action; (2) that the douche should invariably be administered in the supine position, the uterus at the same time being supervised by one hand placed on the abdomen; (3) that, when the administration is completed, the precaution should invariably be taken of ascertaining that the uterus is contracted by palpating the abdomen, and, if distended, the fundus should be squeezed like a sponge in the palm of the hand, and at the same time should be depressed, with the object of evacuating the vagina; and (4) that the surfaces of lacerations about the external orifice should be brought together, and any abrasions which remain should be coated with some material impervious to the solution.

Under the second head, the relative eliminative power of the different excretory organs was discussed, and special attention directed to the condition of the kidneys and intestine. The following suggestions were offered: (1) That chronic nephritis, and probably also those changes which occur in the kidneys during pregnancy, may, by diminished elimination, produce an accumulation in the septum; and (2) that the intestine possesses an equal, if not a greater, eliminating power than the kidneys. With a view to obviate the risks arising from defective elimination: (1) That when the kidneys are affected the sublimate douche should not be employed, or, if used, extreme caution should be exercised; (2) that a free watery flow should be promoted by the kidneys, and that especial care should be directed to this point in hot weather; and (3) that the bowels should be evacuated daily, either by salines or by the administration of such agents as produce copious and loose stools. A tabulated series of eleven cases which presented symptoms of slight mercurialism was appended, and also a fatal case of mercurialism narrated.—*Lancet*, July 14, 1888.

Tamponing the Womb in Septic Endometritis.

At a recent meeting of the Tver Medical Society, Dr. Tzetzilïa M. Tzymkovskaia, the woman-physician to the Tver Gübernsky Zemsky Hospital, read (*Meditzinskoïe Obozrenië*, No. 4, 1888, p. 366) a very instructive paper on two severe cases of puerperal septic endometritis. They refer to a peasant primipara, 18 years old, admitted on the twelfth day after normal labor; and to a servant, 28 years old, brought to the hospital on the fifth day after abortion, and ten weeks after her last menstruation. In the former, adherent placenta and fœtal membranes, and in the latter patient considerable remnants of the fœtus, were found in the uterine cavity, in a highly decomposed state. In both of them, there were present fever (up to 104° F.), extreme prostration, abdominal distension and tenderness, loss of appetite, and an intolerable offensive odor from their genitals, etc. The treatment consisted in washing out the uterine cavity with a corrosive sublimate solution (1:4000), scraping out the whole inner surface of the womb with a sharp spoon, and in tamponing the uterus with a 20 per cent. iodoform gauze, in strips measuring 3¼ and 2¼ yards in length and 2½ inches in breadth, thickly sprinkled over with iodoform powder. The tampon was inserted by means of a uterine sound, after the cervix was dragged downward with a volsellum forceps. It was left *in situ* for three days in both of the cases. The effects were as rapid as striking. The women's temperatures fell down to 99.3° F. and 99.4° F. respectively on the first evening. The offensive odor disappeared immediately. The patients' subjective feeling, appetite, and general state commenced to improve steadily from the very beginning; and the women were discharged perfectly well and sound about seven and five days after their admission. Dr. Tzymkovskaia observes that the antiseptic tamponade of the womb was first practiced in Professor Gusserow's clinic (*vide* the *Centralblatt fuer Gynecologie*, August, 1887) as a hæmostatic measure in cases of puerperal atony of the womb. Her cases, however, brilliantly prove that the tamponing possesses also an admirable disinfecting action. In fact, the tampon not only prevents any putrefaction, but also checks the process—and that even when the latter is in an advanced state. She draws attention, further, to the fact that the procedure is especially advantageous in country practice, since the patient, with her womb tamponed, can be safely left without any troublesome irrigations or injections for two or three days.

Treatment of Xanthoma by Electrolysis.

Dr. Ernest Wende, of Buffalo, reports two cases of this affection in the *Medical Press of Western New York*, September, 1888. In the first case, a married woman, brunette, native of this country, 63 years of age, in perfect general health, applied to Dr. Wende for the removal of xanthoma, whereby she might gain greater cosmetic improvement. The disfigurement was characterized by the formation of two sharply defined chamois-skin-like plaques, one about as large as a three-cent silver coin, occupying the right upper lid near the inner canthus, the other a trifle smaller, which was found almost in a similar position on the left lid. These symmetrical plaques were oval in outline, soft, smooth, and slightly raised over the skin in which they were imbedded.

In the second case a Jewess, brunette, married, 51 years old, general health good, consulted Dr. Wende for a like purpose, the case differing however from the first in that the tumors were of the nodular variety, instead of being flat. There were five in all, varying in size from a pin's head to a pea. Excepting the larger, which was seated on the side of the nose, they were situated on the lids. Knowing that these new formations consisted mostly of fibrous tissue with a deposition of fat, he thought it desirable to destroy the former by the action of electrolysis, with the hope of causing a subsequent disappearance of the whole. For this purpose an electro-negative needle, which was made of gold, was inserted laterally at various points into the neoplastic formations in a direction parallel to the outer surface, and the circuit closed by the ordinary sponge electrode (positive) which was moistened and held in the hand. A current of nine galvanic cells of a twenty-celled Waite & Bartlett galvanic battery was passed through them. After one sitting, lasting twenty minutes, the xanthomatous plaques and nodules darkened in color, and soon dried into eschars. On the eighth day the crusts began to fall off, leaving the skin beneath somewhat reddened; but this gradually faded to its normal aspect, became perfectly smooth, and left no trace of a cicatrix and no remaining vestige of the new growth.

Suture of Nerves and Tendons at the Wrist Joint.

Dr. J. F. Springle reports this case, which occurred under care of Dr. Fenwick in the Montreal General Hospital.

Gabriel D. was admitted to the hospital at 8 P.M. on May 2 last, suffering from a large and deep wound opening the right wrist joint, inflicted by a circular saw. The patient was much weakened by loss of blood when first seen by the House Surgeon.

On examination, a deep lacerated wound, at the back of the wrist, was found, severing all the extensor tendons of the thumb carpus and fingers. The supinator longus tendon, radial nerve, and artery were torn across. The lower ends of the ulna and radius and the proximal line of bones of the carpus were torn and splintered. The flexor tendons and the ulnar artery and nerve were uninjured. At 9 P.M., Dr. Fenwick, assisted by Dr. Shepherd, brought the several tendons and nerves together with fine catgut sutures and fine silk. The arteries were tied with catgut ligature. A quantity of splintered bone and torn ligamentous tissue was removed. The wound was thoroughly irrigated with sublimate solution (1-2000) and its edges brought together with silk. Two drainage tubes were inserted at each end of the wound. The arm was then placed upon a straight splint extending from the elbow to the tips of the fingers, and the wound dressed with iodoform gauze and rubber dressing.

On May 17 he suffered a great deal of pain at the tips of the fingers. The temperature was 99°. The pain was greater at night, necessitating the administration of morphia. The next day he felt easier. Temperature 100°. On the 23d, the wound was dressed for the first time; the dressings were soaked with discharge. The edges of the wound were united in places. A pocket of pus, which had formed in the forearm, was opened and drained. Sensation had returned to the back of the hand and fingers, it having been absent in all except the little and ulnar side of the ring fingers. The limb was dressed and supported upon an inclined plane, the splint being removed. A great deal of sloughing was taking place in the wound on account of the extensive laceration of tissue. On the 28th the wound was again dressed. Sensation had improved; he could feel a slight touch of the finger or the prick of a pin.

The notes taken June 5 state: Temperature has been very irregular, reaching 101° to 103° at night and falling to normal in the morning. Suffers much pain at night. Several collections of pus were opened. Sloughing still continues. Sensation about the same.

On the 8th, sensation was better, temperature was lower, and patient suffered less pain at night. Improvement from this time on was steady.

This patient presented himself at the hospital August 12. He had fair motion of the fingers, and sensation in the back of hand was quite normal. There were still two or three sinuses on the line of the wound, which lead down to necrosed bone. A day or two before the remains of the scaphoid bone were removed.—*Montreal Medical Journal*, Sept., 1888.

Local Anæsthetic Action of Helleborine and Strophanthus.

Venturini and Gasparini, says the *Wiener med. Presse*, September 2, 1888, have made an interesting communication on the local anæsthetic action of helleborine and strophanthus, to the medical society of Sienna. Several drops of a very weak solution of helleborine were dropped into the conjunctival sac of rabbits or dogs; after fifteen minutes complete anæsthesia of the cornea occurred. The cornea could then be cut and even torn without the animals giving the least expression of pain. This complete anæsthesia of the cornea is obtained with three or four drops of a standard solution of helleborine, each of which contains 1-32 grain of helleborine. The anæsthesia lasts half an hour, and leaves behind no disagreeable accompanying symptoms. Anæsthesia with helleborine, they say, deserves the preference over that obtained with cocaine in ophthalmic operations, first, because it only involves the cornea; second, because helleborine acts in very dilute solution and neither irritates the cornea nor the conjunctiva; third, because the helleborine anæsthesia lasts longer than that obtained with cocaine; and finally, because the former exercises no influence upon the pupil and the intra-ocular pressure. When used hypodermically, anæsthesia was obtained at the point of injection; but as it exerts a strong toxic action upon the heart, it needs to be used very cautiously in this way in the neighborhood of the heart. Venturini and Gasparini have further found that a neutral extract of strophanthus hispidus, free from alcohol, produces, even when in very small quantity, a complete anæsthesia of the cornea, which lasts longer than cocaine anæsthesia.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - - -	**1.25**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE CRUELTY OF COWARDICE.

Under this striking title the Louisville *Courier-Journal* recently published an interesting editorial in which it endeavors to combat the prevailing fear of the spread of yellow fever from Jacksonville, Florida. It is not pleasing to note that this editorial speaks in a way far from flattering of the recent behavior of the health authorities of the United States, and of certain cities; but it must be admitted that there is some ground for its criticisms. In the present state of medical science it is pretty generally suspected that yellow fever is a disease produced by the action of a specific germ; but this is only a suspicion, and so far from being a demonstrated fact that it is no wonder those who are somewhat incredulous in regard to germs in general should express a certain contempt for sanitary measures of unusual harshness which are founded upon an unquestioning faith in them. The *Courier-Journal* says truly: "A germ is something terrible to the average imagination, because it is unseen, intangible and unknowable." After this, it proceeds to describe some of the unreasonable and ridiculous steps which have been taken in different parts of the United States to prevent the supposed germs of yellow fever from occupying and devastating the land. These steps, it must be admitted, have been quite as absurd as they appear to the *Courier-Journal*, and they are to be regretted not only because they have a tendency to increase panic and cultivate false notions in regard to the disease in question, but also because they lessen the respect of our fellow citizens for the members of the medical profession.

One of the greatest dangers to science in our day is the disposition to draw important conclusions from inadequate premises. The very process of reasoning is indeed sometimes perverted; the inductive method is abandoned for the deductive, and theories which are still in the stage of hypothesis are treated as if they were formally established. This is exemplified in much which has occurred of late in connection with the yellow fever. The assumption that is caused by a specific germ is as yet only an assumption, and there seems to be some danger that, in the pursuit of this idea, important facts bearing upon the development and propagation of the disease may be overlooked. It may be true—and there is much to make it seem probable—that yellow fever is produced by some form of bacteria; but of this we are by no means sure yet. As we have already said, in the REPORTER, September 22, we trust that the present unfortunate epidemic may yield some useful scientific fruit to offset its sad effects on life and health; but we fear that these fruits will not be matured by much which has been done of late in the name of Science. If we, as medical men, are to make solid advances in our knowledge of this disease, and to

give no cause for such stinging criticisms as have suggested this editorial, we must be careful to avoid committing or endorsing errors which are founded upon unreasoning fear, or hasty assumptions. The case is one for the exercise of the calmest judgment and the most severely logical processes of reasoning. Only in this way can we hope to attain a position from which we may command the respect of our fellow-men and cope effectually with this grave disorder.

As Archbishop Whately says in the Preface to his Elements of Logic: "Truth will, indeed, prevail, where all other points are nearly equal; but it may suffer a temporary discomfiture, if hasty assumptions, unsound arguments, and vague and empty declamation, occupy the place of a train of close, accurate, and luminous reasoning."

THE HOMŒOPATHIC STATE MEDICAL SOCIETY.

The Homœopathic State Medical Society of Pennsylvania has just concluded an interesting meeting in Philadelphia, and has displayed a fitness for the discussion of important medical questions which would hardly be expected by those who are not familiar with the advances made of late by those who bear this designation. In fact, the proceedings at this meeting were so like those of any "regular" medical society that it is hard to discover any homœopathy in them at all. It would appear indeed that our homœopathic fellow-practitioners have studied the developments of medical science to such good purpose that the tenets of Hahnemann have come to occupy but a minor and subordinate position in their thoughts and practice.

The mental attitude of what are known as "advanced" homœopaths is strikingly exhibited in the opening address of the President of the Society, who stated that he had been forcibly impressed at last year's meeting with the following questions: "Does homœopathy constitute the whole of therapeutic science?" "Is the physician best prepared to cope with disease in its varied forms, whose knowledge and use of drugs is always and only confined to their homœopathic use?" "Has the physician discharged his full duty to his patients, in all cases, when he has made the most careful selections of the symptoms in the case?" "May the (homœopathic) medical school, in view of its responsibility in the education of physicians, confine its therapeutic teachings to the homœopathic medication alone?" and added that he had been constrained to answer them all in the negative.

Now, here is a frame of mind which must be gratifying to all who hope to witness the downfall of exclusive dogmas. Were Hahnemann alive to-day, we believe it would fill him as much with distress as it does us with hope. We imagine he would repudiate such sentiments as strongly as we applaud them, but that he would join his voice to ours in urging those who cannot conscientiously follow his teachings to abandon the name which he adopted.

The relation of what is called homœopathy in these days to "regular medicine" has been often enough discussed, and sometimes with so much acrimony that no possible good could come of the discussion; but the time seems to be approaching when the sincere supporters of truly scientific methods in medicine may, with some hope of success, invite those who follow the same methods to give up a name which now separates them from those in whose company they ought to be found, and which misleads only those who do not understand either it or them.

The harsh criticisms which have been applied to those who call themselves "homœopaths" may be deserved by some of them; but we cannot doubt that many of them are actuated by the same motives and governed by the same principles as actuate and govern those from whom they stand apart. These men, like the President of the Pennsylvania Homœopathic State

Medical Society, believe that experience and observation furnish the only rational basis for the practice of medicine, just as we do. They may believe that Hahnemann's theories furnish a useful basis for practice in some cases. But they know that, if this is demonstrated by experience, nothing in the tenets of the old school prevents its adherents from profiting by this knowledge. They know that the main objection we have to what is called homœopathy is that it claims universal or exclusive applicability for a principle which they and we know is not of universal or exclusive applicability. We cannot see how this fact fails to impress all intelligent and conscientious men alike, and why some men to whom these characteristics cannot be denied do not come out from the company of those who are suspected of using the name of homœopath for purely commercial reasons.

We believe the time will yet come when this state of affairs — to which we refer with no unkindly feelings—will cease, and when such men as made the last meeting of the Pennsylvania State Homœopathic Medical Society almost undistinguishable from a similar meeting of "regular" physicians will not debar themselves from association with all other scientific medical men by holding fast to a name which misrepresents them and discredits them in the opinion of men who have no desire to be unjust or uncharitable.

A FAULT IN MEDICAL JOURNALS.

It is with considerable regret that we observe that some of our most respected contemporaries at times relax a little the virtue which usually marks them, and admit to their pages "reading notices" published solely in the interests of their advertisers. One of the most insinuating of these appeared not long since in several of the best medical journals of the country in the shape of a review of a small book, issued by a rich advertiser, which the REPORTER refused to notice because it had no scientific value and was almost wholly composed of testimonials, written by amiable physicians, to the virtues of special preparation.

The objection to this sort of thing is twofold. First, it is no proper material for the reading pages of a publication devoted to so serious a subject as the science and art of medicine. Second, it is never impartial and cannot fail to be unfair, either by an act of commission or an act of omission. A medical journal which would systematically discuss the merits of all commercial claimants for professional approval, might, if gifted with superhuman intelligence and wholly free from bias, serve an excellent purpose; but a journal which publishes only laudatory notices of wares advertised in its pages cannot escape the suspicion of being influenced by mercenary considerations. Unfortunately there are many medical journals in America which do this. Most of them do it—as one frankly admitted—because they are too poor to resist the pressure brought to bear on them by the advertisers.

We wish they had more courage and more strength, for the sake of their readers; and we regret very much that the strain on the weaker and less courageous should sometimes be increased by the conduct of vigorous and prosperous periodicals which ought to be both an example and a support to them.

—Babies are said to be dying so fast in Manchester, England, that the city is aroused over the subject. The great majority are overlaid by parents in bed, four such deaths having occurred during one week. The London correspondent of the New York *Times* reports that "there is a general suspicion that such deaths are wilfully caused or permitted, either for the purpose of getting rid of the child or obtaining club money or insurance. Nearly all the cases occur on Saturday nights, when the parents are more or less stupefied by drink. Manchester's Deputy Coroner makes out a statement which demands legislative consideration. He points out that in Germany parents are arrested and convicted under such circumstances, and says such a law is greatly needed in England."

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

AN ILLUSTRATED ENCYCLOPÆDIC MEDICAL DICTIONARY. BEING A DICTIONARY OF THE TECHNICAL TERMS USED BY WRITERS ON MEDICINE AND THE COLLATERAL SCIENCES, IN THE LATIN, ENGLISH, FRENCH, AND GERMAN LANGUAGES. By Frank P. Foster, M.D., Editor of the *New York Medical Journal*, with the collaboration, etc. Vol. I, with illustrations. A. Cacos. Quarto, pp. xii, 752. New York: D. Appleton & Co., 1888.

It is with great pleasure that we welcome and recommend to the attention of the readers of the Reporter this magnificent work, prepared under the direction of one of the ablest editors in the United States, and published by a house well known to the readers of good medical books. It would be impossible to give an adequate notion of its literary merits in the space at our disposal; but it is enough, perhaps, to say that a careful scanning of its pages and a search for words which occurred to the writer of this review have resulted in the finding of everything to be expected in a book of this character. The comprehensiveness of the book, as a dictionary, is simply wonderful, and the clearness of its definitions is, in the highest degree, creditable to its editor and his able collaborators.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

An Experimental Contribution to Intestinal Surgery, etc. By Nicholas Senn, M.D., Milwaukee, Wisconsin. From the *Annals of Surgery*, June, 1888. 84 pages.

The Weaver Case. By Hampton L. Carson, Esq., Philadelphia. The Case of John Daley. By John B. Chapin, M.D., Ellwyn, Pa. Philadelphia: Published by the Medical Jurisprudence Society.

On the Advantages of Plaster-of-Paris Dressings as a Means of Spinal Support. By Lewis A. Sayre, M.D., New York. From the *New York Medical Journal*, June 16, 1888.

The Result of Antiseptic Treatment of Abscesses Connected with Disease of the Hip Joint. By R. H. Sayre, M.D., New York. From the *New York Medical Journal*, June 16, 1888. 7 pages.

Medical Expert Testimony. By F. H. Darby, M.D., Morrow, Ohio. From *Transactions Ohio State Medical Society*, 1887. 5 pages.

The Physiological Argument in Obstetric Studies and Practice. By A. F. A. King, M.D., Washington, D. C. From the *Amer. Jour. of Obstetrics*, April, 1888. 18 pages.

—Dr. Senn's pamphlet contains an address which he read at the Ninth International Medical Congress, September, 1887. It gives an account of a large number of experiments in regard to a variety of surgical operations on the intestines. It would be impossible in a short space to give any adequate idea of the ingenuity and skill displayed in these experiments, or of their important bearing upon the subject of intestinal surgery. We can only recommend our readers to try to get the pamphlet, and study its contents for themselves.

—These two papers were read before the Philadelphia Medical Jurisprudence Society in May, 1887, and April, 1888, respectively, and were recently published. The first paper contains an account of the proceedings and issue of a case involving the question of the sanity of a Dr. Weaver, which is of interest to lawyers on account of the technical questions raised, and of interest to all men, inasmuch as the result was that a man, who was sane in the opinion of the commissioner who took the testimony, and of a large number of skilled witnesses, was left in the position of being adjudged insane.

Dr. Chapin's paper gives an account of the case of a man who was acquitted of a charge of murder on the ground of insanity, in Washington, D. C., under circumstances very similar to those under which another man, named Webber, was recently convicted in Philadelphia. The story is of especial interest for experts in insanity, and shows how differently different juries will estimate the import of expert testimony.

—The reprint of Dr. Sayre's paper on the Plaster-of-Paris dressing for the treatment of disease of the vertebræ contains also a report of the discussion which followed the reading of it at the New York Academy of Medicine This adds much to its value, as it presents the views of those who prefer other methods of treatment. Some of the latter manifest what may be almost called animosity toward the method which Dr. Sayre's work made, for a time, almost universal. But the fact remains that this method has been of incalculable benefit to thousands of sufferers, and this pamphlet, which contains an account of how he first came to use it, and his present opinion of its value, is of very great interest, and we commend it heartily to the attention of our readers.

—Dr. Reginald Sayre's pamphlet contains remarks he made on May 18, 1888, before the New York Academy of Medicine, in regard to, and advocating strongly, the opening of abscesses dependent upon joint disease, with antiseptic precautions, and the discussion which followed them. Both are very interesting and instructive reading. There can be no doubt that the different opinions held by the various speakers is partly due to their different conceptions of the operation under discussion. Those who opposed the views of Dr. Sayre seem to have underestimated the importance of thoroughly cleaning out the abscess cavity, and removing the diseased tissue which surrounds it. This is such an important part of the operation, that it is not surprising to find that opinions in regard to the operation differ when some surgeons regard it as essential and others seem to have omitted it.

—Dr. Darby makes a strong claim that medical experts should be regarded as *employés* of the Court, and paid accordingly. He also points out the manner in which the subject of expert witnesses is regulated in certain countries of Europe, and the superiority of this manner to that which prevails in the United States.

—We have already, in an editorial in the Reporter, June 16, 1888, called attention to this interesting address by Dr. King, and we limit ourselves now to repeating our commendation of its sensible and admirably put suggestions, and to advising our readers to send for a copy and read it for themselves.

CORRESPONDENCE.

Animal Skin Grafting.

TO THE EDITOR.

Sir: I received this morning a letter from you dated April 27, 1888, which, having but one postmark, I presume had been lying in the interim forgotten in your office.

I am very glad to hear that you consider my modification of Reverdin's plan of skin-grafting of value; but it has been very little used here, apparently for the reason that in populous centres—where it would be most useful—it is difficult to obtain wild rabbits alive, whilst in the country, where they are plentiful enough, the necessity rarely presents itself. The skin of the domestic animal is so loaded with fat that its vitality would be lost before it could be made ready for application; that of the wild is quite free from it and so thin that it can be transferred with the utmost facility: hence its selection. But, since the publication of my *brochure* a countryman of your own has advised the using of the skin of the common fowl and taken from the nearly bare patch under the wings. I regret that I cannot recall his name, and the more so as his suggestion is much better than mine.

The usefulness of either is best shown in treating large denuded areas such as are left after severe burns or contused wounds; an example of the latter class I have had recently in extensive sloughing of the scalp after a fall. In that case it answered extremely well, and I could only regret that the rabbit's fur had not remained permanently adherent, for there is left a smooth bald place of distressing conspicuousness. And Dr. Dolder, the editor of the *Provincial Medical Journal*, wrote me about three months ago that he had made use of my expedient in the case of a sloughed wound four inches in diameter left after an ovariotomy, and that it was almost completely healed within a week.

If it were not for the obstructive action of the Vivisection Act in this country the plan could be made still more useful, for, from a chloroformed rabbit a sheet of skin six or eight inches square could, I believe, be successfully transferred; the animal to be of course killed before it had recovered consciousness. As it is I have not attempted to remove pieces larger than a silver dollar.

I may be permitted to add that I feel especial pleasure in seeing any work of mine noticed in the American press, for I am indebted to the energetic government of the United States for my rescue from a terrible death in Paraguay in 1868, although that obligation was so painfully discounted by the cowardly and wanton brutality of Captain Kirkland who commanded the expeditionary gunboat. Nevertheless I shall ever regard the people of the United States with the most grateful remembrance.

I have the pleasure of sending herewith a copy of my pamphlet, of which pray make any use you may think proper.

Yours truly,

G. F. CADOGAN-MASTERMAN, M.D.

Yorke House, Stourport, England,
September 7, 1888.

NOTES AND COMMENTS.

Simple Way to Test the Acidity of the Contents of the Stomach.

A simple method of testing the acidity of the contents of the stomach is suggested by Spaeth, in the *Münchener medizinische Wochenschrift*, as follows: Cut alder pith into small cylindrical bits and immerse them for twelve hours in a solution of Congo-red (15 parts of the coloring matter to 1000 parts of water), dry them, and put away for test purposes. To use them, first make fast to the end of a strong silk thread a No. 6 shot, string one of the colored cylinders on the thread, and make the patient swallow it—holding fast to the free end of the line, of course; after a few moments withdraw the test pith and the depth of the blue discoloration of it will give an approximate idea of the acidity of the gastric fluids.—*National Druggist*, August, 1888.

Effects of High License in Minnesota.

The *Pioneer Press* gives an interesting review of the results of the first year of high license in Minnesota, and finds that the system has proved to be all its friends asserted of it. It seems that there are in Minnesota only 1,597 saloons now as against 2,806 when the law went into effect. A decrease in the consumption of alcoholic drinks is shown in nearly every county. Low groggeries have been closed up, and the liquor business is under better police supervision. Under the old system the average cost of a license was about $300, and the total approximate income was about $850,000. Under high license the average cost of permission to sell is about $650, and the total approximate income is about $1,100,000.

Cactus Grandiflorus in Heart Disease.

The *Chemist and Druggist*, August 11, 1888, says that this remedy for heart disease was the subject of a recent paper by Dr. Orlando Jones, of Harrogate. Cactus grandiflorus is a native of Jamaica and Vera Cruz. A good description of this plant is given by Grim. Its flowers are remarkable, being very large, the calyx measuring about a foot in diameter. It is possible, Dr. Jones thinks, that other plants of this order may be equally valuable, as possessing properties that will control the heart's action, for Professor Robert Bentley states that the fruits of many species are useful in febrile diseases. Dr. Jones gave notes of cases in which the remedy had been used, and the results appeared to show that this remedy may be used as a substitute for digitalis when that remedy is inapplicable owing to its over-stimulating action, and in cases of feeble heart. The final stage of the action of the drug is that it strengthens the heart, and consequently improves the circulation, so that the result of the exhibition of cactus is the reverse of that seen in digitalis.

Disinfectants that Neutralize Each Other.

Dr. Joseph Holt, formerly President of the New Orleans Board of Health, in a letter on the yellow fever in Florida, recently published, used this language: "When the sulphurous fumigation is used after the wetting of surfaces with the mercuric solution, 'the sulphurous gas' does not 'unite with the mercuric salt forming a compound which impairs the germicidal power of both,' as declared by Assistant Surgeon J. J. Kinyoun, of the United States Marine Hospital Service, in his recent report on the Louisiana quarantine. That officer was sent here as an expert, and has made a positive statement in regard to a point in chemistry without having taken the trouble to try the experiment. When sulphurous-acid gas or liquid, or sulphuric acid, is added to a solution of the bichloride of mercury, there is absolutely no chemical interchange, but the solution remains perfectly clear. A drop or two of the solution of the iodide of potash will reveal the mercuric element by an abundant precipitation."

This is a very important matter, says *Science*, September 14, 1888, on account of its practical bearing on the effectiveness of the two agents mentioned, in disinfection, and the results that follow from using one after the other. Dr. Kinyoun has therefore written a reply, from which the following extracts are taken: "As Dr. Holt is a man who wields a large influence in the Southern country in regard to sanitary matters, I think it only a matter of justice to the public to correct the error that Dr. Holt has himself made in stating that the sulphurous fumes do not form an insoluble compound with the mercuric salt, etc. In this connection I would respectfully state that the fact had been long known to me, even prior to my inspection of the Louisiana quarantine, that when SO_2 is passed through or brought in contact with a solution of bichloride of mercury a change took place. The mercuric was changed to a mercurous salt; and, observing it during the process of fumigation, I confirmed it before submitting my report. Owing to the want of time, I have not undertaken to find out the exact proportion of the constituents due to the re-action. Suffice it to say that the precipitate is calomel.

"It is apparent that, if bichloride solution is used prior to sulphur fumigation, the amount of water alone which is present would absorb a great quantity of the gas, and prevent its penetration where the bichloride solution does not reach; and when the change occurs in the solution of bichloride, it is obvious that the germicidal power of both is impaired. When SO_2 is passed through a solution of bichloride containing an equal quantity of ammonia at the temperature of 25° to 40° C. (77°–104° F.), the change takes place slowly; but when the solution or gas is heated to from 40° to 90° C. (104°–194° F.), the change takes place rapidly, converting nearly all the mercuric to a mercurous salt."

The Treatment of Snake Bites.

Dr. C. R. Earley, of Ridgway, Pennsylvania, writes to the *College and Clinical Record*, August, 1888: "I have treated many cases, and have a record of twenty-five very bad cases, all of which were treated by the free use of olive oil internally and externally. I have never directed any other treatment. The inhabitants of locations where rattlesnakes and copperheads are found always keep a good supply of olive oil in their houses, and when bitten never call a doctor, but use olive oil freely, which in every case gives full and complete relief. Therefore my experience for the past thirty-eight years has fully proven the correctness of the treatment with olive oil of Dr. Miller, of South Carolina."

A New and Rational Treatment for Gonorrhœa.

Under this attractive title, Mr. Charles J. Smith, formerly Surgeon to the Farrington Dispensary, states in the *Lancet*, September 1, 1888, that he has been able to cure his cases of gonorrhœa in five days by using an instrument by which an ointment is made to cover the inside of the urethra. The instrument is modeled after Mr. Allingham's rectal ointment-introducer, and consists of an oblong ointment-container with a long broad screw to expel its contents. To the box are attached perforated stems of different sizes to fit closely the urethra, which he says must be stretched by as large a stem as can be introduced, so as to spread the ointment fairly and well over every portion. The bladder should be emptied immediately before the instrument is introduced, so that the urethra will be well washed out from behind. The stem is well oiled before introduction, and, when once introduced, the screw is turned, the ointment expressed, and the whole instrument rotated as it is withdrawn. He uses a mixture of oil of eucalyptus and olive oil. Three hours after using the instrument, a mild injection (he does not say of what) is used, and the ointment-applicator used again the next morning. The only medicine given is a saline aperient.

The principles applied in this treatment are sound, but Dr. Smith's statement as to their efficiency needs confirmation. Certainly cocaine should be used before the instrument is inserted, not only because the use of the latter would itself be painful, but because the oils are irritating.

Rare Case of Tuberculosis of Sternum.

Professor le Denter recently showed an interesting case at a meeting of the Paris Academy of Medicine. It was that of a man whose sternum and part of the superior ribs were entirely gone, as the result of bone tuberculosis. In order to put a stop to the abscesses that were in progress, M. le Denter removed all the diseased parts of the bones, and the operation was entirely successful. Besides preserving the patient's life, it had the advantage of rendering the man a very interesting object of study for physiologists. The whole of the inferior two-thirds of the sternum being removed, and also part of the anterior extremities of the corresponding ribs, the base of the heart and part of the aorta are very accessible to physiological investigation. This investigation has been carried out, through the methods at the disposal of modern physiology, by Dr. H. de Varigny, under Professors Chauveau and Richet's supervision; and the result is, that very fine graphic representations of the aortic pulsation have been obtained, which are quite identical with those obtained on higher animals. — *Popular Science News*, August, 1888.

Paris Doctors and Signs.

The Paris correspondent of the *New York Med. Journal*, September 1, 1888, says: One of the rather curious facts in regard to medical customs in France is the difficulty a stranger has of finding a physician's house, notwithstanding the fact that Paris has as large a proportion of physicians as any other city—not excepting some American ones. The greater number display no sign, and when you know that in Paris one house is as like another as two peas, it is easy to imagine the trouble of finding the right house when on the search for a doctor. Not only is there no "shingle" on the front door, but there is not even one on the door leading to the office—not even a card to show the stranger who lives in the *appartement*. We were told the other day of an American's search for a celebrated French specialist's office. He had the world-wide known name well enough, but could not pronounce it as they do here. However, by writing it, he found the boulevard, and, fortunately, he had the right number, but here again his troubles began, as he did not understand the polite "concierge's" instructions as to which floor the doctor occupied. Nothing daunted, our Yankee friend mounted the stairs, hoping to find at least the family name on a little silver plate on the door, but, alas! after mounting seven flights he could see no sign. Determined not to be beaten, however, he wrote the name on a paper, and, commencing at the first floor again, he conscientiously rang at all the doors until he found the right one. Among all the thousands of physicians who practice in Paris, *not one*—except the English and Americans who practice here—has his name on his own door, nor on the street door. Among the cheaper class of physicians will be found a small sign saying "*Docteur en médecine de 1 à 3 heures*," but no name is given; and as to the better class, not the slightest indication is given that they live in a house. It is a curious Parisian custom.

Strophanthus in Heart Disease.

Fraenkel, Guttmann, and Langgaard have recently given the result of their experience with strophanthus. Fraenkel believes that it modifies blood pressure and causes diuresis, diminishes dyspnœa, and is a genuine cardiac drug. He has employed it in twelve cases of valvular disease, two of arterio-sclerosis and hypertrophy of the left ventricle, three of simple cardiac weakness, and three of chronic nephritis. Four of the first set were relieved by the administration thrice daily of from five to fifteen drops of the tincture; the others were not benefited. The second and fourth groups were not benefited, but the third was greatly relieved.

Dr. Liddell, of Winchester, had two cases of degeneration, in each of which the heart and general condition of the patient were markedly ameliorated not only during the time strophanthus was administered, but also after the cessation of treatment. In some cases of failure of the circulation, strophanthus gave little if any relief, and on administering digitalis benefit resulted. In elderly people with degeneration of the arteries and the heart beating vigorously; dyspnœa with palpitation; the pulse feeble and more easily compressible than usual—strophanthus failed to give relief; digitalis was then given, and brought about marked benefit.

Strophanthus has in several of Mr. E. G. Dutton's cases produced an intermittency in the heart's action, always relieved by increasing the dose—an effect not mentioned by other observers. The salicylates can be given in combination with strophanthus when they cannot be borne alone on account of their depressing action on the heart. He thinks it of inestimable benefit in inorganic heart affections.—*Quarterly Therap. Review*, July, 1888.

Use of Opium in Young Children.

Roth (*Bulletin Médical*) has proved that opium given to young children, even in very small doses, produces convulsions which may become fatal. It also, when given to the mother, produces movements in the fœtus which are to be recognized as convulsions. Roth cites a case illustrating this: in a pregnant woman who had received large doses of opium the movements of the child became in a short time powerful and almost unbearable. Roth therefore thinks that the employment of opium for the prevention of abortion is irrational.—*Deutsche med. Wochenschrift*, August 2, 1888.

Tannic Acid in Burns.

Nikolsky (*St. Petersburger med. Wochenschrift*) has employed, in 18 cases of burns of the first and second degree, applications of an alcoholic solution of tannic acid, with very good results. He orders:

℞ Acidi Tannici . . . . . ℥i
Alcoholis (95 per cent.) . q. s. (circ. f℥i)
Etheris sulph . . . . . f℥i
M. Put the mixture in a vessel with a glass cork.

The burned part is cleansed with a disinfectant, then the tannic acid is applied until a firm film is formed (by coagulation of albumen), and this is repeated two or three times a day, as often as this film cracks. The whole is then covered with a dry compress. Blisters are cut, the contents expressed with cotton, the surface of the wound dusted superficially with iodoform, and then painted with the solution of tannin. Pain is usually diminished and the treatment does not last long.—*Deutsche med. Wochenschrift*, August 2, 1888.

Damages for Infection with Syphilis.

In the Paris law courts recently, the parents of a child suffering with hereditary syphilis, which communicated the disease to its nurse, were condemned to pay about $400 damages to the woman. Each of them has also had to pay a fine of about $20. The decision was grounded on the clauses of the Code providing for the punishment for wounds or other injuries inflicted through carelessness. It appears that the parents were aware of their child's condition.—*Medical Press and Circular*, September 5, 1888.

Cocaine and Nitrite of Amyl.

In the case of a vigorous man who had to be operated on for hydrocele, M. Ounkorsky (*Vratch*) injected two Pravaz syringefuls of a solution of hydrochlorate of cocaine (one part in twenty-five). The following phenomena appeared: Restlessness, lumbar pain, pallor, vertigo, weakness of the voice, oppression, feebleness of the pulse, general weakness, loss of power in the extremities, all objects seemed uniformly white to the patient. This condition lasted for an hour when nitrite of amyl was employed by inhalation. The patient inhaled altogether about fifteen grains of the substance, and received besides three injections of sulphuric ether—a Pravaz syringeful at each injection. In half an hour afterward, all the symptoms of cocaine poisoning disappeared.—*Bulletin Médical*, July 8, 1888.

Antipyrine and Cocaine in Child-birth.

In a letter to the *Bulletin Médical*, July 8, 1888, a correspondent relates a case in which he injected into the abdominal walls of a woman a solution of antipyrine and cocaine, for the purpose of relieving the pain and distress attendant upon child-birth. The amounts employed seem very small—about six grains of antipyrine and about one-twelfth grain of cocaine. The effect was to produce great calmness and a painless delivery. No bad effects, such as headache and ringing in the ears, were produced. The conclusion is suggested that antipyrine calms the pain due to the uterine contractions without arresting their progress. On the other hand, it may be that, the apprehension of suffering being removed, the patient is in much better condition to assist in the delivery.

Contribution to the Pathology and Therapeutics of Leukæmia.

In an elaborate article on this subject in the *Zeitschrift für klinische Medicin*, 1888, XIV, 80–147, Sticker reports in fullest detail a fatal case which had been under observation eight months, and on which numerous scientific studies were made; and then discusses some of the symptoms of the disease. We may note that, as regards the blood, the case teaches that the increase or decrease in the number of the white blood-cells keeps pace with changes in the symptoms, except the constant growth of the spleen—or rather that it precedes them somewhat. This case further shows the greatest number of white blood-cells yet reported, equalling at one time 3,743,000, or a proportion of 1 : 0.5. The smallest number of red blood-cells in leukæmia is reported in a patient of Sorensen and Quincke, and equalled 500,000 in the cubic millimetre. The case of Sticker also confirms the statement that the number of the white blood-cells increases, as that of the red diminishes; and is against the oft-repeated assertion that there exists a diminution in the volume of the blood. There is rather a hydræmic plethora. The frequency of the pulse and of the respiration appeared to be nearly independent of the general condition of the patient. Toward the last, there existed a profuse bronchial catarrh, which was found to consist almost entirely of the "eosinophilous" cells; while, at the same time, the number of white blood-cells was found to have diminished decidedly, and it is almost certain that they were eliminated by the bronchial tubes. Priapism was present, as in many cases, but had certainly nothing to do with the genital function. No fatty degeneration of the organs was found which is in contradistinction to anæmia, and confirms Cohnheim's statement. The retinal changes, which were extensive, are detailed at length. Late in the affection, there was disease of the labyrinth of the ear.

The author made an elaborate investigation into the metabolism in his case, as shown by the analysis of the urine, and found that during the whole eight months it was abnormally great, and increased with the growing cachexia. Urea and uric acid were always in excess. The increasing number of the white blood-cells certainly has an important relation to the increased elimination of nitrogen. It is very probable that the degeneration of the liver which was present produced a diminution of the formation of urea, and an increase of that of uric acid; but it is certain that it was not able to paralyze the agents which would cause an augmentation of the first and a lessening of the second. The enlargement of the spleen had nothing to do with the increased excretion of uric acid.

As concerns the treatment, the author believes that the very marked improvement, which was seen for a time, was undoubtedly due to inhalations of oxygen; a case having been also reported by Kirnberger, in which recovery followed this treatment. This treatment may do good by supplying oxygen to white blood-corpuscles, which otherwise consume all they have before the tissues can profit by it. It has been proved that the leukæmic organism has a diminished oxidizing power. The rôle of arsenic in the therapeutics of leukæmia is not yet positively determined, and needs further study. Quebracho was of great benefit in this case in relieving the severe dyspnœa, and has been also recommended by Fleischer and Penzoldt.—*American Journal of the Medical Sciences*, July, 1888.

Formula for Saccharine.

M. Constantin Paul, at a meeting of the Therapeutical Society of Paris, July 25, 1888 (*Bulletin Médical*, August 19, 1888), said the following formula made a good elixir of saccharine:

Saccharine	℥ iss
Bicarbonate of soda	℥ i
Alcohol (at 40°)	f℥ iii
Essence of mint	gtt. xx

M. Sig. Coffeespoonful in a glass of water.

NEWS.

—The *Western Druggist*, Sept., 1888, says: Dr. Kauffman claims to have solidified petroleum by heating the oil, and adding to it from 1 to 3 per cent. of soap, which dissolves in the oil. The liquid, upon cooling, it is said, becomes like tallow, and is hard to light, slow to burn, and without smoke, but develops much heat. The petroleum is then available for fuel.

—The Colonial Surgeon of Hong Kong says the experience obtained in the Hong Kong jail is that the habit of opium smoking is far less deleterious than spirit drinking. Old confirmed smokers were found to have preserved a good appetite, and it was further found that the suffering attendant on the deprivation of opium, which is not allowed to anyone in the prison, was not more than in the case of a tobacco smoker deprived of his pipe.

—The Philadelphia *Ledger*, September 8, says: Dr. Sophia Jex-Blake, of the Edinburgh School of Medicine for Women, has successfully passed all the examinations of the Edinburgh Extra-Mural School before a committee of the conjoint Colleges of Physicians and Surgeons, and thus occupies the status of a lecturer on midwifery in the Extra-Mural School. It is believed to be the first instance of the admission of a woman lecturer on this branch in a public school.

—The *Medical Record*, Sept. 1, 1888, says: "A large number of soldiers in a regiment stationed in one of the French fortifications recently exhibited symptoms of poisoning by belladonna. An investigation undertaken to discover the source of the poison showed that it could not be in the water or wine drunk by the troops, for all the garrison had the same. In the absence of a better explanation, it was attributed to the eating of some unripe potatoes containing solanine."

—The *Medical Record*, Sept. 29, says that the Trustees of the Eastern Dispensary in New York City are about to hold examinations for the purpose of filling the following positions: One Attending Physician to the Department of General Medicine, one Attending Surgeon to the Department of General Surgery, and two District or Visiting Physicians. The Attending Physicians will be required to render two hours daily service at a salary of $400 per year, and the District or Visiting Physicians are to serve two and one-half hours daily at a yearly salary of $500.

HUMOR.

His Intention was All Right.—What an ardent prayer was that of the colored brother who besought the Lord to *an' int* his congregation with the "ile" of Patmos!—*Harper's Magazine.*

If your house is overrun with plumbers, the easiest and simplest method of extermination is to burn the house. To secure yourself, the house should be well saturated with insurance before the match is applied.—*Ledger.*

Where Ignorance is Not Bliss.—Emily. "Oh, Arthur, how cruel! See that poor worm wriggle!"

Arthur. "That's all right. I cut him in two first, so he's perfectly dead, only he hasn't discovered it."—*Harper's Magazine.*

A man who was cured of rheumatism by working around dynamos tells the *Electrical World* about it. He was knocked down very often by shocks, and was once unconscious for ten minutes. He thinks the worst case can be cured. The average sufferer would rather have the rheumatism.—*Ledger.*

Nothing Sharp to Cut With.—Young father: "Blamed if I know what's the matter with the baby, doc., but she cries all the time." Doctor: "Perhaps she has been cutting her teeth." Young father: "I don't believe it, doc.; she ain't had a knife or anything sharp to play with since she was born."—*Judge.*

Works Both Ways.—Customer (to boy in drug-store): "Have you anything for the removal of superfluous hair?" Boy: "Yes, sir; there's a bottle of our celebrated Hair Elixir. One dollar, please." Customer: "But that's intended to make the hair grow." Boy (whispering): "I know that's what it says on the label, but you take my word and try a bottle."—*Texas Siftings.*

One night recently a young man boarded an Albany steamer for New York with his mother, who had never traveled on water, of which she had a horror. The old lady's step became more and more tremulous as she approached the boat, and, after some hesitancy and expressions of her fears of seasickness, she was escorted aboard and safely deposited on one of the comfortable cushions in the saloon. Her son then left her, and, returning half an hour later, inquired how she felt. She answered: "I am deathly sick. Can't you do anything for me?" The son replied: "Mother, the boat has not yet left the dock." In imagination she had been tossing on the deep, but the son's reply cured her sickness.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

W. H. WALMSLEY & CO.

SUCCESSORS TO R. & J. BECK,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

THE

Zentmayer Binocular Microscope

IS NOT SOLD YET.

2 EYE-PIECES. 2 OBJECTIVES. (8-10 and 1-5.)
THE REGULAR "HISTOLOGICAL" STAND.

In good order. Can be used as a Monocular or Binocular—either. **$50 will buy it.**

Will be sent by express without extra charge.

Clinical Lecture.

RECURRENT PELVIC PERITONITIS.[1]

BY B. F. BAER, M.D.,
PROFESSOR OF GYNECOLOGY IN THE PHILADELPHIA POLYCLINIC.

Gentlemen: This patient is thirty-two years of age, and has been a widow two years. She has never been pregnant. The duration of the present illness is uncertain. Ever since puberty she has suffered more or less from the symptoms of which she now complains. She presented herself ten days ago, and stated that she was scarcely able to be out of bed, but being unable to employ a physician she felt compelled to go to a dispensary.

Her chief symptoms were sharp pains beginning in the left iliac region, deep-seated, and shooting across to the opposite side. She said the pain began with the onset of the last menstrual period, and that the flow was much more profuse than usual. Her menses usually last four days; at the last period the flow continued seven days, and was profuse, as stated. On questioning her it was learned that she had had numerous attacks of a similar character since puberty, especially in connection with the menstrual periods, and that of late years these attacks had been increasing in severity, the last one being the most severe she had had. The pain is at times almost unendurable. She becomes pale, and often during the attacks she suffers from nausea, and sometimes from vomiting. There is also some distension of the abdomen, with tenderness on pressure. The pain is less severe if she occupies the dorsal position, and she finds that bending the thighs upon the abdomen affords relief.

The question of differential diagnosis is an interesting one in a case of this character. You will note that the pain here is continuous and not intermittent in character, and that position and pressure increase rather than relieve it. If you will recall a case which we had in the clinic a week ago, you will remember that the symptoms somewhat resembled these, in the time of their occurrence—at the menstrual period—and in the sharp character of the pain. But in the former case there would be an attack of severe cramp-like pain in the centre of the hypogastrium or a little to the side, which would continue for a variable time, to be followed by a discharge of fluid or clotted blood, when there would be an interval of relief, to be followed by another attack. The pain was relieved by pressure; the patient stated that pressure gave her more relief than anything else, and that when the menses ceased she was apparently well. In the present case it is different. After the cessation of the flow the patient is unable to be about for days, and does not recover from the soreness and tenderness, but is more or less ill during the entire interval between the periods. In the first case we found stenosis of the cervical canal, and determined that the symptoms were due to obstruction in that canal so that the menstrual fluid could not readily flow out. We diagnosticated in that case congestive dysmenorrhea the result of stenosis. In the present case we found a different physical condition. The symptoms here are inflammatory in character and point to a local

[1] Delivered at the Hospital of the Philadelphia Polyclinic and College for Graduates in Medicine.

peritonitis, more especially of the left side, possibly, but not necessarily, involving the left ovary and tube. The pain of pelvic peritonitis is sharp in character and radiates from the affected side to the opposite, and often down the anterior portion of the limb, especially when the ovary and tube are involved. The symptoms here also resemble somewhat those of so-called ovarian neuralgia, except that in the latter case pressure relieves instead of increasing the pain; and the disorder is not attended by increase in temperature, and is not followed by exudation, although it usually produces nausea and vomiting.

This patient states that she began to suffer at the time of the occurrence of puberty; and on questioning more closely, we find that the symptoms at first resembled more nearly those of dysmenorrhea, the result of stenosis, due to an imperfection in development. They have since, however, gradually changed to their present character, which I ascribe to pelvic peritonitis; and as the trouble recurs with the menstrual period or from other cause, the disease has been properly termed "recurrent pelvic peritonitis." It recurs for the reason that the original cause and its consequences are still active.

It is probable in a case of this character that there is more or less inflammatory action with every period of ovulation, which is relieved or modified by the occurrence of the menstrual flow, which depletes the congested vessels and ends the process for the time. At the following period there may be an attack just as severe, and each succeeding attack may be more severe than the previous one, until the patient becomes so ill that she is compelled to call her physician; when, if an examination is made, it may be discovered that the uterus is only moderately fixed from a slight film of exudation on the peritoneal surface, or the exudation may be so great as to present a hard, board-like sense to the touch; or indeed the peritoneal pouch may be distended by an exudation so large in quantity as to present a well-marked tumor, such as we find in this case. The tumor formed in these cases is without shape, or rather it is not circumscribed by a smooth wall as in fibroid or ovarian tumor, but rather takes the shape of Douglas's pouch or the post-broad-ligament space. It is usually a little thicker below than above, but the general shape is flat. Both the ovary and the tube of the affected side may be involved in the inflammatory condition and surrounded by the exudation. In that case the tumor would be of somewhat different character. It would be larger, and probably circumscribed, but still irregular and fixed.

It has been said that this disease always begins as a vaginitis or endometritis, and extends to the Fallopian tube, finally involving the ovary and peritoneum. When abscess of the tube or ovary is found to exist in connection with the peritonitis, the origin is usually ascribed to gonorrhœal infection; when not attended with the formation of pus it is still said to be due generally to some septic material, non-specific or otherwise, admitted through the same channel.

There can be no question that this is true in many instances, probably in the majority of cases; but I believe it is also true that the disease often arises from traumatism, the result of congestion from interference with the menstrual flow, such as occurs from obstruction in the cervical canal, from stenosis or flexion of the uterus. The injury may also arise from coition, or from an external blow; or from cold, resulting in suppression of the menses. Obstruction in the cervical canal may result in regurgitation of menstrual blood through the Fallopian tubes into the peritoneal cavity. The obstruction may also be in the tube itself as the result of malformation of that organ; or the narrowing may be from inflammatory or other cause. Again, there may be such malformation of the fimbriated extremity of the tube as to prevent its grasping the ovary at the time of the rupture of the Graafian follicle. In the latter case the contents of the follicle would be discharged into the peritoneal cavity, and might result in the development of peritonitis. Early rupture of an extra-uterine gestation sac is another traumatic cause.

We must explain the development of the peritonitis in some cases from causes other than specific or infectious. This patient, for instance, first complained when she began to have her menses, and I do not think it would be scientific to jump to the conclusion in cases such as this that the disease was of gonorrhœal origin. It is not likely that at the early age of puberty a specific cause existed, and it would be unjust to the patient to ascribe it to that origin. It is more likely that the origin of the disease in this case has been in one of those developmental or traumatic causes enumerated above.

But whatever the cause, when called to a case of this character, you should at once make a physical examination, for the purpose of determining the locality and extent

of the disease, so that a proper treatment may be adopted. The patient should be at once placed in bed, for rest is one of the prime factors in the management of the case. If great pain and tenderness exist, a hypodermic injection of morphia should be administered. This will relieve the pain and facilitate the examination. If the necessary manipulation cannot be made without it, ether should be administered. The question to be settled first is the diagnosis, and I wish here to impress upon you the necessity of gentle manipulative measures, for I do not think there is a doubt but that many cases have been injured and made worse by a rough and awkward examination. First administer an antiseptic vaginal douche for the protection of both the patient and yourself, and see to it that your hands and instruments are rendered aseptic by thorough washing and emersion in an antiseptic lotion before they are used.

This patient was examined at her first visit ten days ago, and I found the uterus moderately fixed. On the left side and in the post-broad ligament-space there was a semi-solid mass of lymph extending into Douglas's pouch, flattened in shape and quite tender on pressure. It was not nodular, and seemed to become thin toward the upper portion, and to be of the general shape which you might imagine would be given to liquid glue or plaster of Paris which had been poured into a mould shaped somewhat as the post-uterine space is. I made a diagnosis of recurrent pelvic peritonitis, and ordered the patient to bed. I also ordered certain medicines, the first and most important of which was a saline laxative. For the relief of pain she was given a vaginal suppository as follows:

℞ Morphinæ sulph. . . . . gr. iii
Ext. Belladonnæ . . . . gr. iii
Ol. Theobromæ q. s.
M. et ft. supposit. No. vi.

Sig. One, morning and night for pain, if necessary.

She was also ordered the following mixture, to be used as a local application over the painful region.

℞ Tr. Aconiti rad.,
Tr. Opii . . . . . āā ʒi
Tr. Iodi . . . . . ʒvi

M. Sig. Poison. For *external* use only. Apply with brush to painful surface as directed, twice a day.

She was requested to paint the affected area with this mixture very thoroughly twice a day. The next most valuable remedy in a case of this character is the hot water vaginal douche, but it was omitted here because of the fear that it would not be administered properly, and might consequently result in more harm than good.

The patient was seen several times in the interval. She reports to-day that she is better, and that the pain has almost entirely disappeared. This will enable us to make a more thorough examination, and if possible, determine the cause of these recurrent attacks. The patient is placed in the dorsal position, and with the left index finger well warmed and lubricated I will proceed to make the examination, and describe to you the condition which I now find. In the first place, I am glad to be able to state that the semi-solid exudation tumor in the post-broad ligament-space, which was found at the first examination ten days ago, has almost disappeared; but in its place there is a hardened, irregular mass, which renders the tissues in this region fixed and rigid. I now place the fingers of the right hand on the hypogastrium, and by the conjoined manipulation which is permitted to-day, because of the absence of great tenderness, I am enabled to explore the post-uterine space more thoroughly. I discover in Douglas's *cul-de-sac* an indurated mass, irregular in shape, which is simply an extension of that which exists in the post-broad ligament-space. I am unable to outline the ovary or Fallopian tube, or any circumscribed or cystic condition resembling disease of those organs. I infer, therefore, that they are probably not involved in the inflammatory process.

I find on examination of the cervix uteri that that organ is somewhat enlarged, and that the os is very small—so small, indeed, that I can scarcely detect it with my finger. The body of the womb is also enlarged and firm, but it is mobile, only the cervix being fixed by the indurated exudate described a moment ago.

The absence of the semi-solid tumor which I discovered at her first visit, does not prove that I was wrong in my diagnosis, but simply that the serous portion of the mass has been absorbed, leaving the indurated irregular condition of the exudated material, which we find to-day. That is the history in these cases. Nature attempts, as soon as the inflammatory process has reached its height, to restore the parts to their normal condition by resolution of the exudate; but nature only partially succeeds, for another attack usually supervenes and arrests the process. Another attack supervenes for the reason that the original cause still exists, and also because the remains of the previous attack serve as an abiding stimulus to a

recurrence. The original cause of the disease in this case I believe to have been contraction or stenosis of the cervical canal, as described.

What will be the proper course of treatment in the present case under the existing circumstances? Will it be proper for me to begin at once a treatment for the purpose of rendering the cervical canal patulous, so that the menstrual fluid may escape naturally? If that means dilatation, I say emphatically No, for the manipulative measures which are necessary for the performance of the operation of dilatation would very probably cause a renewal of the disease.

As a rule patients who suffer from chronic pelvic peritonitis, which this practically is, are more or less broken in general health. They are more or less the subjects of nervous exhaustion, indigestion, anemia, and loss of flesh, as a result of the long suffering endured during the course of the disease. I believe that here the most efficacious plan of treatment is that which embraces REST as its guiding principle. It is unquestionably true that when the patient is allowed to exercise and follow her usual vocation, the attrition of the inflamed surfaces upon each other will tend to keep up the inflammatory condition. It is best, whenever it is possible, to remove the patient from the cares of her home, so that she may have mental as well as physical rest, free from domestic cares and especially from the marital relation. A general regimen, similar to that which was introduced by Dr. S. Weir Mitchell for the treatment of nervous exhaustion, and which consists of seclusion, rest, and diet, together with massage and general electricity, is the one which is most beneficial in these cases, whilst the local treatment which is necessary is being carried out.

Strict attention should at once be paid to the condition of the bowels, for constipation is one of the most troublesome accompaniments of pelvic peritonitis. I believe it often stands in a causative relation, and nearly always as a complication of the disease; first attention should be paid to the relief of this condition. Strict attention should be paid to the diet, and the food should be of the most nutritious character.

The local treatment should embrace those remedies which are thought to possess the power of stimulating the absorption of plastic material, either by a counter-irritant or stimulating action. The persistent and free use of the tincture of iodine, both to the hypogastrium and the fundus of the vagina, is of great value. But iodine alone is sometimes found to be so irritating to the skin as to make it necessary to discontinue its use; for that reason I am in the habit of prescribing the formula as given above, consisting of the tinctures of aconite and opium in addition to the iodine. This may also be applied to the fundus of the vagina instead of the iodine alone, either with a camel's hair brush or with the cotton-wrapped applicator. The vaginal application of the iodine should be made not oftener than every three days, and sometimes a longer interval is advisable, especially if the remedy is used in a concentrated form. If it is found that too much irritation has been produced its use must be discontinued for a time, and then remedies of a milder form may be substituted, such as the boroglyceride, or iodoform and glycerine, one drachm to the ounce, or glycerine alone may be used.

The remedy which I consider next in value to iodine, if not indeed preferable to it, is the hot water douche. But this remedy is liable to be abused when placed in the hands of the patient herself. It is a remedy the use of which should not go out of the hands of the physician or his trained assistant, the nurse. When administered by the patient herself the water is either used at too low a temperature or in too small quantity, or both. Further, she becomes tired of the pumping and of the position which she must assume, and fails to keep it up during the length of time required for the injection of the quantity usually advised—a gallon or two. The constrained squatting position is in itself injurious. I believe that the long continued use of warm water is followed by relaxation of the pelvic organs, and this would constitute another objection to the indiscriminate recommendation of this measure; for when it is placed in the hands of the patient, she is likely to continue its use for too long a period and after the indications for its use have disappeared. The remedy must be used in accordance with fixed rules, and under certain restrictions, and these I would class as follows: First. The patient must be in the recumbent posture, and in the dorsal position. Second. She must not administer the douche herself. Third. The water must be at a certain *high* temperature, which is best determined by the sensations of the patient. It should be as hot as can easily be borne, and the temperature gradually increased during its administration, for the patient will be able to endure it at a higher temperature after the current has been flowing a few minutes than when it is first begun.

I believe the douche is better than pumping, by Davidson's syringe for instance, because the application is more likely to be thorough and the effect to be maintained longer. For, even when the injection is given by the physician or nurse, the hand is liable to become tired of the pumping and the application stopped, for a time at least. It is the continuous application of the remedy which is most beneficial. For use in my private hospital, I have had made a tri-pod, five feet in length, with a hook in the center on which a bucket is easily hung. The bucket holds two gallons of water, and near the bottom is placed a stop-cock, to which is attached a tube provided with a nozzle and a stop-cock at its distal end.

The patient is placed on a bed pan, which I have modified after that devised by Meriman. The nozzle is then introduced into the vagina, and the stop-cock at the bucket turned by the nurse, the water being at a temperature of at least 110° F. The patient can then regulate the flow herself. The water is allowed to enter the vagina, dilating it, and flowing off slowly, so that the tissues are in a continuous hot bath, which can be kept up as long as desired—from ten minutes to half an hour or longer—care being taken to see that the proper temperature of the water is maintained by the addition of a fresh supply from time to time. The important point is not so much the amount of water, as its temperature and constant contact. The application of this remedy should be made once or twice a day, depending on its effect upon the patient.

Recently I have been using "Gordon's Utero Vaginal Irrigator." This instrument does away with the necessity of the pan, which is a great improvement. The mechanism of the instrument is simply the placing of a bulb similar in shape to that portion of Davidson's syringe which is used for the pumping. This bulb is placed near the end of the vaginal nozzle; its position, therefore, is in the orifice of the vagina, filling that space so that the water cannot escape except through a return tube which passes through the bulb. To this return tube a piece of rubber tubing is attached of sufficient length to conduct the water into a receptacle on the floor. With this instrument the water can be used at a much higher temperature, because it does not come in contact with the surface at the orifice of the vagina, which surface is more sensitive to the heat than that within the canal. Then another great advantage is the getting rid of the necessity of the pan. With these precautions in its administration, hot water is one of the most valuable remedies which we possess in the treatment of pelvic inflammations, and great credit is due to Dr. Emmet for introducing it and his persistence in keeping the remedy before the profession.

After all tenderness has subsided, much may be accomplished by gentle massage of the adherent pelvic organs, but great care and gentleness are necessary in the manipulation for fear of producing such irritation that the inflammatory process may be renewed. Then it is very necessary that organic disease of the Fallopian tubes and ovaries should be excluded before massage is begun, for if pyosalpinx or abscess of the ovary should exist and be overlooked, rupture of an abscess might result from the manipulation.

Before massage is begun, the patient should be placed across the bed, the hips resting a little over its edge and the feet placed on the knees of the operator. This relaxes the abdominal muscles, and gives greater control of the patient, so that the necessary manipulation may be thoroughly carried out. One or two fingers of the left hand should now be introduced into the vagina, while the fingers of the right hand are placed upon the hypogastrium; then the contracted ligaments, thickened membranes, and fixed uterus, ovaries, and tubes should be gently manipulated, and moved from side to side, or upward and downward, care being taken that the force used is not sufficient to lacerate adhesions, or even to so stretch them as to cause undue irritation. The proper amount of force is probably best regulated by the sensibility of the patient, and if pain is produced by the manipulation it should not be persisted in. This massage may at first be employed at intervals of two or three days, but later it may be used almost daily for a time. By this method it will almost invariably be found that the adhesions become attenuated and in many cases finally absorbed. On the other hand, in long-standing chronic cases, the adhesions may be of such size and strength that months may be required to produce any marked effect; and in rare cases the adhesions may be of such character as to be permanently organized, and almost incurably to fix the organs. Here operative measures of a nature to be described in a future lecture may be necessary.

In these marked chronic cases I have found, in addition to the massage, that

stretching of the fundus of the vagina, by firmly packing it with antiseptic wool, sometimes repeated daily, or at intervals of two, three, or four days, is of great benefit in overcoming the condition. The small rubber colpeurynter, distended with hot water, is a very efficient means of accomplishing the stretching, and I have used it with great satisfaction in some cases.

It has been advised that continuous pressure and stretching of adhesions be made by means of a large pessary; but I would strongly urge against such practice, for I do not think that good ever comes from it, and it is certainly often attended with harm.

There is another means of stimulating absorption in these cases of pelvic exudation which is now attracting considerable attention. That is electricity, both by the galvanic and Faradic currents. I have been using Faradism during the last few years in many cases of this character with benefit, and during the last year I have been using galvanism. This I have found to be of value in stimulating the absorption of exudated material. I think that it will eventually take a prominent place, when properly understood and properly applied, in the treatment of these cases, as well as in the treatment of fibroid tumors. There is no doubt as to the power of the strong galvanic current, applied according to the advice of Apostoli, to modify the nutrition in fibroid tumors, and generally to ameliorate the symptoms. I have had some marked cases to support these views. The same will apply to cases of pelvic exudation, and, I believe, also to some cases of disease of the tubes and ovaries which have not advanced to the formation of pus. Where pyosalpinx and abscess of the ovary exist, the only remedy is the removal of the diseased appendages by laparotomy. But I wish here emphatically to state that I do not believe that pelvic peritonitis is always the result of endometritis or salpingitis, nor that removal of the appendages is always necessary to effect a cure. I learned early in my experience the great value of prolonged rest and thorough local and general treatment in these cases. Benefit always follows, and in many cases a cure. As much cannot be said for removal of the appendages. In many instances removal of the tubes and ovaries in these cases does not cure the patient. I have, at the present time, under my care, for the same symptoms of which they complained before the operation, two of my own cases and several that have been operated upon by others. If that is the experience of one individual, it is probably the experience of all, and will swell the number of uncured cases to many. Do not understand me to say that I am opposed to the removal of incurably diseased uterine appendages, which cause great suffering to the patient, after other proper means have been used to effect a cure; for I am an advocate of the operation in such cases, as you have seen. But I plead for conservatism and due deliberation, and the exhaustion of means which do not subject the patient to an operation which is attended with danger to her life, and by which she is unsexed, so far as fertility is concerned; for many cases will get well without an operation, if time is given and skilful treatment faithfully pursued.

COMMUNICATIONS.

SULPHONAL; THE NEW HYPNOTIC.

BY HENRY M. WETHERILL, JR., M.D.,
ASSISTANT PHYSICIAN PENNSYLVANIA HOSPITAL FOR THE INSANE.

In the treatment of mental and nervous disorders it is of great importance to possess for insomnia a remedy of which sleep is the predominant physiological action. The medical profession has been waiting anxiously for the ideal hypnotic, and it seems as though the new German drug sulphonal approaches, in its effects, nearer to the ideal than any other of the recently discovered substances with which the modern, and especially the German chemists have filled the market. The claim to superiority of this new substance is that it has little if any physiological effect upon the vast majority of insomnious persons, except the important one of increasing and prolonging the natural tendency to sleep. Its action is said to be not in the least narcotic, but purely hypnotic. It is claimed for it that the pulse, pupils, temperature, respiration, appetite and secretions are unaffected, after its continued daily use, for an indefinite period; and that, finally, it is promptly eliminated from the system, principally by the kidneys, without irritation or detriment to those organs. It is a crystalline, white substance, with a slight tendency to efflorescence when exposed to the atmosphere, and is readily pulverizable, emitting, only when strongly triturated, a slight odor of sulphur; it is almost wholly tasteless, producing no dryness in the throat, and no unpleasant after-taste. It somewhat resembles urethan in appearance, and is formed in the process of the oxidation of

acetone in the presence of sulphur, and hence the odor when it is warmed or rubbed. Sulphonal is singularly insoluble in the potable solvents, such as water, the dilute acids or dilute alkaline solutions, or very dilute alcoholic fluids. It is soluble in a mixture of two parts of alcohol (ethylic, 95%) and one part of ether; but this is not potable, and any dilution of this with water precipitates the sulphonal.

In the estimate of the therapeutic value and effects of a drug, surely water is the only fair solvent, and if it cannot be a solvent, then it should be at least the vehicle employed, if it is desirable to exhibit the drug in a liquid form.

Sulphonal may be administered in powder, or a dose of the finely powdered substance may be suspended in three or four fluid-drachms of cold water, by means of gum arabic and syrup. This mixture should be thoroughly shaken before it is used, and but one dose prepared at a time, as the sulphonal rapidly settles to the bottom of the container.

The name sulphonal is composed of syllables picked out of the word which expresses its chemical composition—diæthyl-sulphondimethylmethan. Its actual solubility is in the proportion of one part to about one hundred parts of cold, and one part to eighteen or twenty parts of boiling water (which, of course drops it as it cools). It is unaffected by acids, alkalies, or oxidizing agents—a very stable compound. The following is its symbol—$(CH_3)_2.C(C_2H_5.SO_2)_2$. This substance was discovered and named by Prof. Baumann, who with Prof. Kast of Freiburg, tested its physiological action first on dogs, afterward upon normal human beings, finally upon insomnious persons, insane and otherwise. Their clinical observations proved that in doses of from two to three grammes (30 to 45 grains), given to persons in health, it produced lassitude, hebetude, sleepiness: when given in the same doses to persons suffering from nervous and febrile insomnia it produced a sound and refreshing sleep of from five to six hours duration, within from one-half to two hours after its administration. Subsequently, Prof. Cramer and Dr. Rabbas obtained similar results in a series of clinical observations upon insane patients in the Marburger Irrenheilanstalt. In no instance was its effect unpleasant or dangerous and it did not produce any evil after effect upon the circulation, respiration, appetite, digestion, secretions or excretions. The pupils and vision remained unaffected.[1] "Although somewhat slower in taking effect than chloral hydrate, the action of Sulphonal is more prolonged. Doses of two to three grammes proved safer and more effective than proportionately larger doses of amylene hydrate. Another peculiar and valuable attribute in sulphonal is that the prolonged use does not weaken its physiological effect; nor does it produce the desire for a narcotic that makes the use of chloral (and some other drugs) so dangerous. Additional and general investigation which will follow its introduction, will, no doubt, verify the above outlined observations, and insure the popularity of this new hypnotic."

The papers of Prof. Kast and of Dr. Rabbas were published in 1888, in the *Berliner klin. Wochenschrift*, April 16 and 23. Rabbas (see REPORTER, June 23, p. 823) considers it more desirable than paraldehyde or amylene hydrate, and as compared with chloral hydrate, sulphonal is less prompt and less profound, but more lasting in hypnotic effect. There is an unusual unanimity of opinion among all the investigators as to the merit of the new drug, and further evidence of clinical and physiological work will be found, as follows:—that of Langgard and Rabow, in the *Therapeutische Monatshefte*, for May, 1888; of Salgo in the *Wiener med. Wochenschrift*, No. 20; of Rosin, in the *Berliner klin. Wochenschrift*, April 30; of Œstreicher, *Ibid.*; of Cramer, in *Münchener med. Wochenschrift*, June 12, 1888, page 395; of Schwalbe, in *Deutsche med. Wochenschrift*, June 21, 1888, page 499, and of Rosenbach, in *Berliner klin. Wochenschrift*, June 11, 1888, page 481. Œstreicher thinks it better to give the dose several hours before bed-time, as it is rather slower to act than some of the other medicines of this class; but he found it none the less reliable in his hands, especially among the insomnious insane. Cramer's cases were all of the latter class. In 407 trials on 92 insane subjects he had "positive success" in 92.6 per cent.—*i. e.*, from 5 to 9 hours of unbroken sleep, occurring in about a half-hour after its administration. He had not an instance of unpleasant effect, "though in one case one ounce in six days, and in two others forty-five grains daily, for two months, were given." The published investigations of Schwalbe are of especial value and reliability, as they seem to have been thoroughly exhaustive and very carefully tabulated. He selected 50 patients, ill of various physical and some of mental diseases and disorders, all insomnious, and obtained a "prompt

[1] Notes on New Remedies, for June, 1888.

and satisfactory" hypnotic effect in 66 per cent.; a "relatively poor" result in 24 per cent., and a "negative" result in but 10 per cent.; but what is of especial value from our point of view is the fact that of 24 cases of purely nervous insomnia, success was complete in 90.3 per cent.

To such cases it seems best adapted, for in instances in which the sleeplessness was the direct result of pain or of decided irritation, success attended his efforts in but 44.4 per cent. Schwalbe agrees with the original observer Kast, that sulphonal is purely hypnotic, not narcotic. It seems decidedly most valuable in perturbed nervous and unbalanced cerebral conditions; but in no sense does it overcome insomnia the result of considerable pain or topical irritation. It does not, for instance, either diminish or allay the nocturnal cough of phthisis or bronchitis. Contrary to the experience of Kast, Schwalbe found it did not relieve cardiac dyspnœa. In but 12 per cent. of all cases investigated were there any ill effects, and these were confined to slight headache, or to transient vertigo. Schwalbe's experience with it in children was most satisfactory, in the dose of four grains. In male adults he gave it in doses of from fifteen to thirty grains; in female adults in less doses, from twelve to thirty grains; but in many adults of both sexes, much larger doses, from thirty-five to fifty grains were well borne, but were seldom necessary.

In the Department for Females, of the Pennsylvania Hospital for the Insane, its assistant physicians have been observing carefully its action upon a group of 8 patients with mental disorder, all of whom had been very insomnious persons; *all* resisting the sedative and hypnotic powers of the bromides, paraldehyde, urethan, tinct. hyoscyamus and valerian. Four of them resisted chloral hydrate and opium, in usual doses: all of them were controllable (i. e. slept) by hyoscine hydrobromate. All of this group are examples of subacute or chronic mania, melancholia or dementia; and all were much accustomed to the use of sedatives and narcotics, and always have to have "night medicine." *But one moderate dose* of sulphonal, suspended in water by means of gum arabic and syrup, was given to each patient about an hour before bedtime, and in no instance was the dose repeated later in the night. The group slept under intelligent observation.

The effects were carefully noted, and reduced to a tabular statement. The medicine was administered 230 times to these 8 individuals, an equal number of times to each. In every case but one, the dose was fifteen grains. In that case (one of well-known resisting power) the dose was twenty grains. The results were as follow: An excellent effect, *i. e.*, from 5½ to 9 hours of continuous sleep, in 196 instances, or 86 per cent. A fairly good effect, *i. e.*, from 4 to 5 hours of continuous sleep, in 15 instances. An imperfect effect, *i. e.*, from 2 to 3½ hours of continuous sleep, in 9 instances, and no hypnotic effect in 10 instances.

It is gratifying to note the general improvement which attends the regular nightly sleep produced by such a singularly harmless drug as sulphonal appears to be. In no instance has its administration (for many continuous nights) been followed by unpleasant effects. The patient rises with the usual appetite, free from headache or vertigo. In no instance did it produce an appreciable effect upon the pulse, temperature, respiration, skin, kidneys, or pupils. The digestion of food was not impaired by its regular use. Its sole appreciable physiological action was *sleep*, usually very restful and prolonged.

Now, if it has been used with so much good effect in overcoming the insomnia of chronic hospital cases of insanity, which have been plied with various sedatives until their susceptibility to the power of drugs is much weakened, and their power of resistance strengthened, how much more sleep-producing effect would a less dose induce in the simply nervous and weary or overworked and irritable nervous system? Would it not be also very valuable in the insomnia of disease of which severe pain is not a factor? Sulphonal will not ease pain, nor will it induce sleep when pain is present as a continuous sensation; but it will allay nervous restlessness, vigilance and excitement.

In regard to dosage, male adults require, as a rule, considerably more than adult females. Our commencing dose with the latter was eight grains, which was soon increased to twelve grains; but these doses were generally found insufficient, and further experiment proved the average effective amount to be fifteen grains, though there need be no fear in increasing the dose, if required, to the amount of from thirty to thirty-five grains. These observations were conducted with care, and are being continued. The results obtained in three members of the group referred to were from observations made by Dr. Henry B. Nunemaker, the remainder by the writer.

AN UNPREMEDITATED CÆSAREAN SECTION.

BY WILLIAM VARIAN, M.D.,
TITUSVILLE, PA.

On July 17, 1888, I was visited in my office by a medical practitioner of extensive practice, over thirty years experience, and considerable local reputation as a surgeon, and one who had been surgeon of a regiment in active service throughout the war of the Rebellion. He stated that he had a patient with an ovarian tumor, who, he thought, demanded operative treatment; and that he had referred her to me, as he himself did not do abdominal surgery. The doctor said he was well assured of his diagnosis, and had had the patient more or less under medical supervision for some months, although he had just arrived at the conclusion that she was suffering from an ovarian tumor. As this was not the first case of abdominal tumor referred to me by this physician, and as I had found his diagnosis on former occasions correct, I had no reason to doubt his diagnostic skill.

I saw the patient on July 18, and obtained the following history. She had been ailing for eleven months, suffering principally from distress and pain in the right iliac region. During the earlier months she had been nursing an invalid mother, and thought that her distress was due to the lifting and fatigue incident to her occupation. She first became conscious of an enlargement on the right side of the abdomen in April. It steadily increased, and during the past few weeks had been growing rapidly. Menstruation was regular in period and in duration, although less abundant than it had been a year ago. This statement was confirmed by an aunt who was present and who did the family washing.

The patient had never suffered from nausea or any disturbance of the stomach. Functions of the bowels, kidneys, and bladder had always been normal. She had never been obliged to rise at night to empty her bladder, except once, a week before my visit, when she had been feasting on watermelon during the evening. No frequent micturition during the day at anytime during her ailment. Her appetite and digestion had always been good; she had lost flesh rapidly of late, especially in the face and shoulders, and had never felt any abnormal sensation in the abdomen—no starting or jumping; no movement nor any sensation other than the pain and distress low down in the right side of the pelvis and region of the right ovary. Her breasts had always been large, and had not increased in size so far as she was aware; nor was there any darkening of the nipple and areola.

This was the history as obtained from the patient and her family. The young woman was thirty-three years old, bright and intelligent, a member of the Baptist Church, and held in high esteem by prominent and wealthy members of that congregation. Her answers to my questions were prompt, clear, and free from any apparent reticence. Neither in countenance nor in manner was there anything which would lead to a suspicion that her frankness was assumed.

The physical examination was made with the patient clothed only in her night-dress. The abdomen was about the size of a woman in the eighth month of pregnancy. The enlargement was principally on the right side. Palpation and percussion gave all the signs of an encysted dropsy. No thickening and enlargement or solid portion could be detected. Auscultation gave absolutely negative results. On vaginal examination I found the os rather long and firm, and was unable to reach the junction of the body and neck so as to trace the continuity of the two. The pelvis was filled above the brim with a fluctuating mass, which by combined abdominal and vaginal examination gave all the signs of a pure cyst. I had some difficulty in passing the uterine sound. The sound passed only 3¼ inches, and, when moved, apparently carried the womb with it. My diagnosis was cystic tumor of the right ovary. Two subsequent examinations during the following week, which were confined to abdominal palpation and percussion, gave no reason to change the diagnosis; and further questioning did not elicit anything to raise a doubt.

On July 30, 1888, I operated, with the assistance of Drs Barr, Young, and Luke, of this city. On reaching the cyst and evacuating a large amount of fluid, I discovered that it contained a fœtus. I promptly enlarged the abdominal opening, incised the uterus, and delivered a living child, which was presenting by the breech, and was evidently an eight-months fœtus. I rapidly removed the placenta, dilated the os from within with the index finger, and closed the incision as quickly as possible with silk sutures closely approximated, avoiding the mucosa. After perfecting the toilet of the abdomen, I closed the abdominal wound with silver sutures, inserting a

glass drainage tube in the lower angle, and dressed the whole aseptically.

The next day some blood was withdrawn from the tube, and the abdomen thoroughly washed with warm sterilized water. The following day the drainage tube was withdrawn, as all oozing had ceased. Eight hours after the operation the temperature rose to 101° F., and the pulse stood at 110. The next day, at 8 A.M., the temperature was 99 3-10° F., and pulse 100. From this time on both pulse and temperature were normal. Convalescence was uninterrupted, and on the twenty-first day after the operation the patient rode out in a carriage.

The child throve at first. There was a total absence of milk secretion. The child was fed artificially, and on the fifth day very *injudiciously* and in exact opposition to orders. A severe diarrhœa was the result, to which the infant succumbed on the seventh day.

The intense mortification felt by me at my error in diagnosis is but little modified by a successful Cæsarean section. That I was deceived by a breech presentation, unusual development of the amniotic fluid, an anomalous condition of the os uteri, and wilful misrepresentations on the part of the patient is more apparent to me than it will be to my critics. It is no consolation to know that other and more experienced members of my profession have met with similar experiences. Yet I freely present my mistake to the profession, that others may learn that it is not impossible even for the experienced surgeon to be deceived.

I failed to recognize the uterus when it was first reached partly because of its pallor, of the smallness of the exploratory incision, because of my inability by digital examination, after the cyst was reached, to detect anything but fluid contents, and perhaps still more because only four weeks before this operation I had successfully removed an ovarian cyst which so closely simulated a pregnant uterus in appearance that nothing but an unnecessarily large incision enabled me to decide that my original diagnosis was correct. My experience in this case satisfies me that the Cæsarean section is no more to be dreaded than other laparotomies, if opportunity is afforded to elect the time of operation.

—Dr. Frank P. Fry, says the *St. Louis Med. and Surg. Journal*, October, 1888, will occupy the chair of Anatomy in the St. Louis Medical College, made vacant by the death of Dr. B. J. Primm.

TREATMENT OF DYSMENORRHŒA BY MENTAL SUGGESTION OR HYPNOTISM.

BY ARTHUR C. HUGENSCHMIDT, M.D.
(UNIV. OF PA.), PARIS, FRANCE.

The following cases pertaining to the subject of gynæcology have occurred in my practice during the past year, and have been treated successfully by this method.

Case I.—Young woman, 27 years old, menstruated for the first time at the age of 11 years; since then her menstrual periods have been very regular, but each one of them is accompanied by a great deal of pain. Five or six days before the appearance of the flow, she has the usual unpleasant feelings described by most patients; but two days before, the pains become terrible, unbearable, the patient being compelled to lie down. These pains are situated in both ovarian regions, are very severe, and shoot down from each side into the corresponding thigh; they are accompanied by severe vomiting and headache. These symptoms last until the appearance of the flow, when the patient looses a great deal of blood, and then the pains disappear. From the train of symptoms alone, some organic malformation of the uterus or displacement of the same could be suspected; still I made no examination as different treatments had been tried before without success. I proposed to try the influence of mental suggestion.

This being assented to, both by the patient and her parents, I began the extremely short treatment in December last. On my first attempt to hypnotize her, I obtained no result by making her look at a diamond ring; on the second day, however, using the same method I obtained a better result, a light sleep, which is all that is necessary for the purpose. While the young woman was in this condition, I contradicted every one of the symptoms, which had been described to me, saying, "that she would have no more pains, no more vomiting, no more headache before, during or after her menstrual periods, that she was now entirely cured; she was then restored to consciousness.

At her next menstrual period, which came on a few days later, she felt perfectly well, had no pain, no headache, and no vomiting. The cure has persisted up to the present day; she has had no more return of her troubles and remains perfectly regular. In this case, these severe symptoms had lasted continuously for sixteen years; and five minutes time has been sufficient to effect a cure.

Case II.—In May last, I was called to a young woman, 25 years old, who complained of a very severe pain in the right ovarian region; the parts were painful to pressure. She had been in that condition for two days, and could walk about the room only with great difficulty, as any movement of her right limb would increase the pain; the symptoms present indicated a probable congestion of the right ovary.

Hypnotism was proposed as treatment and accepted; in this case, sleep was obtained by asking the patient to fix her attention upon my index finger; it took me about four minutes to place her in the proper condition, which is, as stated before, a slight hypnotic sleep. When in this state, I told her that the pain in her right side had disappeared from this moment; that she would be able to move her limb and walk about the room without any aid. On awakening, the patient stood up, began to walk, moved her right limb freely, and said she did not feel the least pain. Since then, these pains, which before would come on occasionally, have not returned.

Case III.—A young woman, 28 years old, menstruated for the first time when 12 years old; the menstrual period is very irregular in time, but not painful. When 19 years old, without any known cause, her menses suddenly disappeared. This amenorrhœa lasted one full year; then her menstruation appeared again. irregularly as before, but is now accompanied at every menstrual period by severe pain and vomiting.

The symptoms were as follows: three to five days before the flow, a general sense of lassitude, swelling of the breasts, and the ordinary signs of approaching menses; the flow then makes its appearance, and only three to four hours afterward do these extreme pains come on. They are, as in the first case, a double ovarian pain, extremely severe, extending down both thighs; the severity of those pains produces a general coldness of the surface of the body. In addition there is severe vomiting, but no headaches; these extreme pains last from six to eight hours, during which time the patient remains in bed, the legs flexed on the abdomen, especially the left one. Poultices produce a certain amount of relief. I hypnotized this patient in less than two minutes, she being a perfect subject. It is needless to say that a third person must always be present during this treatment—one of the family, especially if a young woman is the patient. As in the preceding cases, I announced the disappearance of the ovarian pains and vomiting at the next menstrual period, as well as the complete cure of the patient. Three days later, the patient menstruated, but experienced no pain whatever, and no vomiting; she felt bright and happy during the whole menstrual period. It is only two weeks since her last illness, but I have no reason to suppose that this patient will be cured in a less degree than the two preceding ones. I must add that these three patients were all well educated and very intelligent; hence the suspicion of having had to deal with persons of a low intellectual power is out of the question.

The method of treatment by mental suggestion is a very easy one, and does not, as is erroneously supposed, require a supernatural power on the part of the physician; any practitioner, who will study the subject, can do as well as any man living who uses this process.

Society Reports.

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING, AT WASHINGTON, D. C., SEPTEMBER 18, 19, 20, 1888.

Tuesday, Sept. 18, Morning Session.

The Association was called to order at 10 A. M., by the President, Dr. D. Hayes Agnew, of Philadelphia.

The first business was the delivery of the President's address, which was published in the Reporter, September 22.

The next paper was

A Contribution to the Study of Excisions of the Larger Joints,

by John Ashhurst, Jr., M.D., Professor of Clinical Surgery in the University of Pennsylvania, Surgeon to the Pennsylvania Hospital and to the Children's Hospital, Philadelphia.

(ABSTRACT.)

The remarks which follow are based upon the records of 120 cases in my own practice in which excisions of the larger joints have been required, and will refer especially to the operative method, the after treatment, and the functional value and limitations of applicability of excision in the case of each articulation. The 120 cases embrace 4 of shoulder joint, 19 of elbow joint, 40 of hip

joint, 51 of knee joint, and 6 of ankle joint excision.

Shoulder Joint. My four cases of shoulder joint excision have all terminated successfully; they all occurred in adults, three times in young persons, and once in an old person. The only case of special interest was that of a young married woman, aged 30, admitted to the hospital in a very prostrate condition, with acute necrosis of the left humerus and consequent pyarthrosis of the corresponding shoulder joint. The upper half of the humerus was removed at the first operation, and 20 days afterward the entire remaining portion of the bone including the condyles, the only osseous tissue left being a thin shell of small extent which adhered to the periosteal sheath on the inner surface. The patient recovered rapidly and acquired a surprising amount of use of the affected limb, and the increasing firmness showed that at least partial reproduction of bone was occurring. With the elbow supported, the patient could use her wrist and hand with considerable freedom.

In excising the shoulder joint, or more strictly speaking, the head of the humerus—for the glenoid cavity rarely requires more than superficial scraping or gouging—I have employed the method by a single longitudinal incision. I have endeavored to avoid wounding the tendon of the long head of the biceps, but when the parts are matted together by long-standing inflammation, the tendon is difficult to recognize and is often not seen until it has been severed.

In the after treatment, I attach much importance to the use of the well-known cushion devised by Prof. Stromeyer. It keeps the elbow out from the trunk, thus insuring the close application of the sawn humeral shaft to the glenoid cavity, and enables the patient to sit up or lie down at pleasure, without disturbing the dressings.

The functional utility of the limb after excision of the shoulder joint is upon the whole, quite good. The operation although seldom called for in civil practice, should be adopted without hesitation in suitable cases, such as those of suppurative arthritis, caries and necrosis, in which the indication for the operation is found either in pain, or in exhaustion from profuse purulent discharge. For plastic or rheumatoid arthritis or for simple anchylosis, the operation is not to be recommended, for the mobility of the shoulder compensates measurably for the stiffness of the joint, and the gain which would be obtained by operation is not sufficient to justify the risk.

Elbow Joint. Of the 19 cases of excision of the elbow joint, six have terminated fatally: 2 adults died within five days from traumatic gangrene following injuries so severe that amputation would have been the better operation; one died of delirium tremens; two from tubercular meningitis; and one, an old man, from exhaustion in the course of the fifth week.

In excising the elbow joint, I employ a longitudinal incision on the inner side of the articulation, taking care not to wound the ulnar nerve and to retain the attachment of the biceps. As a rule all the articulating surfaces should be removed, and within reasonable limits, the more bone that is taken away, the better, since flail-like union is less to be dreaded than anchylosis.

For the after treatment, I employ a somewhat obtuse angled, internal splint (Physick's splint) well padded and protected by oiled-silk. As bony union is to be avoided, it is not necessary to use a splint to render the part immovable. As soon as the external wound has become solid, the splint should be abandoned and the arm kept in a sling.

The functional result of a successful excision of the elbow is more nearly perfect than that of excision of any other articulation. Cases which justify this operation, are those of destructive, or gelatinous, arthritis, caries, necrosis, compound dislocation or fracture not so severe as to require amputation, and even simple anchylosis.

Hip Joint. I have 40 times resorted to excision of the hip joint in 37 patients. Twice have I excised, at intervals, both hip joints in the same individual, and once have I had recourse to re-excision in a case in which recurrent caries and recontraction followed some months after the patient left the hospital. This case terminated fatally from suppurative osteo-myelitis and septic peritonitis, at the end of a fortnight. Both cases of double excision did well. Of the 40 operations, 28 were followed by recovery, 11 by death, and one of the patients is still under treatment. Of the 37 patients, 25 recovered and 11 died. Should the patient now under observation die, the rate of mortality will be, as regards operations, 30 per cent.; as regards individual patients, 32.4 per cent.—a much better showing than the results given by most statistical writers.

The incision employed begins with a straight cut in the direction of the fibres of the gluteal muscle, curves around and behind the trochanter, and terminates in a straight cut corresponding to the axis of the femur. While affording free exposure to

the joint, it necessitates but little transverse division of muscular fibres. The head of the bone may be made to protrude, and then removed with the chain saw, or, under other circumstances it may be divided *in situ* with a small saw. It is my custom to remove both trochanters, and to round off the sawn end of the femur. In the *after-treatment*, I keep the limb well adducted with simple weight extension, with lateral support by means of sand bags. As soon as the external wound has become solid, and the patient can control the motions of the limb, he may be allowed to get about on crutches.

The functional result of hip joint excision must be somewhat differently judged from that of excision in the case of other articulations. In most instances the operation is performed only when death seems threatened by profuse suppuration or its consequences, and if the patient is relieved of pain and restored to a fair state of health and comfort, the treatment is amply justified. At the Children's Hospital in Philadelphia, where 20 of the 40 operations were performed, the rule is: not to operate, except in otherwise hopeless cases; and hence our recoveries represent so many lives saved. But in many cases excision not only saves life, but also restores the patient to the active duties of existence. In thirteen of the twenty-eight cases the patient obtained a useful limb, and in two of these the utility is regarded as perfect. The condition which most often calls for this operation is "hip-disease." I consider the operation suitable in certain cases of gun-shot injury. For uncomplicated anchylosis, it is not to be recommended, simple osteotomy being here a safer and surer method. Where anchylosis co-exists with extensive caries or necrosis, excision may properly be resorted to. I am afraid that the "age limit" for hip joint excision must still be maintained; in the case of the knee, I have ventured to extend the benefits of this conservative procedure to adults and even to middle-aged persons, and with great success; but excision of the hip joint becomes an operation of great and rapidly increasing gravity when once puberty is passed. Thus, while I count twenty-five successes and only four deaths in persons under fifteen years of age, I have had only three recoveries and no less than seven deaths in those older. In adults, the operation should only be undertaken with a clear understanding of the very great risks by which, under these circumstances, it is attended.

Knee Joint. I have performed 51 excisions in 50 patients, once having employed re-excision for anchylosis with recurrent deformity, in a case in which I had excised the joint nine years before. Once I amputated the thigh, ten weeks after excision, on account of beginning failure of health, and a good recovery followed. Of the 51 cases, but 5 have ended fatally, a death-rate of less than ten per cent.

In excising the knee joint, I have uniformly adopted the single transverse incision and have invariably removed the patella. The bone sections are commonly made with a Butcher's or bow saw. I take special care to remove all of the diseased synovial membrane as well as all patches of carious bone. In treating the large bursa beneath the quadriceps muscle, I have endeavored to hasten the cure by making a long incision on the outer side of the limb and either dissecting the bursa out bodily, or else scraping away its lining membrane with a sharp curette. If foci of softened and carious bone are found beyond the points at which it is safe to use the saw, I remove them with the gouge, and if necessary cut a channel through the osseous wall in such a way that the part may heal firmly without leaving a sinus.

In the after treatment, I employ a bracketed wire splint which, while firmly fixing both thigh and leg, enables the limb to be dressed as often as is needful without causing the patient pain. I have left the limb on the splint as long as six or seven weeks. After bony union is well advanced and the external wound is almost healed, I substitute a simple posterior splint or gutter of paste board. I think it important to use means of mechanical support for at least six months, especially with children.

The utility of the limb after successful excision of the knee is very great. The limb is stiff and slightly shortened; the foot is sometimes a little inverted, but the limb is strong, painless, and enduring, and enables the patient to lead an active useful life. As a substitute for amputation, and it is as such that I employ it, the merits of knee joint excision can not be gainsaid.

The cases in which excision of the knee joint is indicated are chiefly those of arthritis, especially of the variety for which years ago I suggested the name gelatinous; of caries; of neglected epiphysitis, etc. The operation may properly be performed in anchylosis with deformity, and also in certain instances of wound of the articulation where the extent of the injury

is limited. In most traumatic cases, however, I believe that when any operation is called for, amputation will be found preferable.

Ankle Joint. I have resorted to this operation six times. Although about as often, I have removed the astragalus without interference with the tibia and fibula. Two of the six cases proved fatal from phthisis, one four months and the other nine months after operation. My impression is that this operation in itself is attended with very little risk.

In excising the ankle joint, I make an external incision curving around behind and below the outer malleolus, and carried forward as far as can be done without endangering the extensor tendons, and prolonged upward as far as needful in the line of the fibula. A second smaller incision is made longitudinally over the lower end of the tibia. It is usually desirable to remove the whole astragalus. This is perhaps the most tedious and difficult of all excisions, and the operation may be facilitated by rendering the part bloodless by the use of the Esmarch apparatus. The ankle is the only joint, with the exception of the wrist, in the excision of which the use of this apparatus seems to me to be desirable.

Some years ago I devised a bracketed splint for the after treatment of ankle joint excisions. This answers a good purpose. If antiseptic dressings are used, however, the part usually requires so little disturbance, that a simple posterior gutter of paste board supplemented by a fracture box, will be sufficient. The foot should be kept at right angles with the leg.

The cases which seem to me to call for ankle joint excision are those of compound fracture and dislocation, less severe than to require amputation, and those of localized caries and arthritis in which there is no suspicion of general tuberculous infection.

The large majority of my excisions have been performed without any of the so-called "antiseptic precautions" and the wounds have been dressed with simple oiled lint or with lint saturated with dilute alcohol. For more than a year past, however, I have employed the antiseptic method in almost all my large operations, using also antiseptic dressings in their after treatment and I think with benefit; though I am obliged to say that as regards the ultimate welfare of the patients, I have not noticed any gain. My best series of consecutive successes has been obtained under old methods, and I have not obtained any diminution of mortality by the adoption of the new. At the same time I have seen no ill results which could be attributed to the use of antiseptic measures; their use shortens the period of convalescence; and they have the merit on account of the infrequent change of dressings needed, that they greatly lessen the surgeon's labor. I know of no cases which require more personal and unremitting attention than those of excision, and it is an unquestionable advantage to be obliged to dress a wound only once a week, or every other week, instead of daily or every other day.

What will be the future of the operation of articular excision? The brighter triumph of conservative surgery in the hands of Fergusson and his successors, will it keep its place? or as some of our more enthusiastic brothers prophesy, will improved methods of dealing with joint disease in its early stages, make excision a matter only of surgical history and of antiquarian investigation? It seems to me that as the introduction of excision did not enable surgeons to abandon amputation for articular lesions, so improve treatment as we may, and educate the public as we may as to the necessity of being treated early, there will always remain a class of cases in which only by sacrificing a part, can we hope to save the whole, and in which excisions of the larger joints will therefore still be resorted to by judicious and conservative practitioners.

In opening the discussion, Dr. Lewis A. Sayre, of New York, said: The paper of Dr. Ashhurst has so thoroughly covered the ground, that very little is left to discuss. In excision of the hip joint I have been in the habit of using the wire cuirass, for the reason that it permits the carrying of the patient into the open air—an object not readily attained when the patient is kept in bed with the ordinary apparatus.

In regard to the antiseptic treatment which I practice entirely, I think that I may claim that I have used it without knowing it, from the time that I commenced practice of surgery. I think that my success has been largely due to the practice of pouring into the wound Peruvian balsam, which from the creasote (*sic*) it contains is an excellent antiseptic. I have also always arranged for thorough drainage. When I practiced my first excision in 1854, the operation was universally condemed. Some seem to now be going to the other extreme and performing excision of the hip joint too early, before a thorough trial of local and general treatment has been employed.

Dr. R. A. Kinloch, of Charleston, said: There is now no disagreement as far as the general question of excision is concerned, but there are still some important questions to be considered: In the first place, the distinction of traumatic from pathological cases amenable to operative procedure, and in the next place as regards the joints which are apt to do best in connection with excision for traumatism and for pathological processes. A consideration of the age and surroundings of the patients is of importance. Probably the best results follow excision in connection with shoulder joint excision for traumatism. In connection with gelatinous inflammation of the elbow joint, I have had satisfactory results even where all the material could not be removed.

I feel sure that if a few of the principles of so-called antiseptic treatment, cleanliness, thorough drainage and absolute rest, are adopted, many of the details may be omitted.

Dr. T. F. Prewitt, St. Louis, insisted on the necessity of getting cases of excision in broken down children out of doors as soon as possible.

Dr. F. S. Dennis, New York, called attention to cases of excision of knee-joint for disease beginning in abscess in the condyle. In these cases the abscess cavity breaks down after recovery, leading to the production of deformity. In these case he takes away all of the abscess cavity, saws away a corresponding piece from the tibia and brings the oblique surfaces together.

He has been in the habit of employing antiseptic dressings, removing the drainage tube on the third day, allowing the first dressing to remain five or six weeks.

In excision for injury, only enough bone to allow of free drainage should be removed.

Sir William MacCormac, of London, had heard with some surprise that the tendency seemed to be postpone excision of hip-joint until all other measures had failed. This is not the practice in regard to any other joint. In England the disposition is to perform the operation at an earlier period. Another point that he had not heard mentioned in the paper was in reference to the performance of operation in cases of old dislocation of the joint. He had performed this operation with success in old hip joint dislocation, and reported the case of a sailor coming under observation three years after the occurrence of dislocation of hip joint which had not been reduced. After the operation he could use the limb perfectly. He had been much interested in the recommendation of Dr. Ashhurst that a long incision be made to reach the subcrural bursa, a suggestion which he had not heard mentioned by any other surgeon.

Dr. E. M. Moore, of Rochester, had been somewhat surprised to hear a certain amount of indifference expressed toward the use of antiseptic surgery. He had found in his practice the greatest improvement follow the use of antiseptic dressing in these cases of excision. He cited several cases showing the result obtained.

Dr. John E. Owens, of Chicago, agreed as to the value of the wire cuirass and referred to a modification of this apparatus consisting in the substitution of a frame of gas pipe conforming to the outline of the body. On this the body is supported by means of flannel stretched between the two sides of the frame. Extension may be applied if desired by the use of adhesive plaster, counter-extension being provided for by elevating the foot of the frame. After keeping the patient in bed for 30 days, he tries to get them into the open air. He had found great advantage in keeping up a certain amount of extension after the patient was allowed to get up. By removing pain this enables the patient to move the joint more freely and thus tends to favor greater mobility of the part. He thought that there was no comparison between the antiseptic methods and those formerly employed.

Dr. Fred. Lange, of New York, referred to a class of cases in which the disease of the hip began in the tissue outside of the joint, the articulation becoming involved at a later stage of the affection. In these cases he recommended early operation, with the hope that in this way necessity for opening the joint would be avoided.

AFTERNOON SESSION.

The Association was called to order at 2 P. M. by President Agnew. The first paper was entitled

The Relation of Micro-organisms to Injuries and Surgical Diseases,

by Dr. Nicholas Senn, of Milwaukee. The paper was so extensive that in the limited time alloted to its consideration, the author was able to refer to but a few of the points which it contained. At the present time no argument is required to show that many special conditions are due to the presence of bacteria. In regard to the so-called

hereditary transmission of disease, the author held that the specific microbes of the specific diseases are transmitted directly from parent to child. In evidence of this he referred to cases of so-called hereditary osteomylitis in newly-born infants. In other cases while this same origin may be inferred we have as yet no direct evidence that such is the case. In regard to the question whether or not pathogenic micro-organisms exist in the healthy body, while the results of some observers point in this direction, the results of others are opposed to the existence of pathogenic organisms in the healthy body. The conclusion was that under certain circumstance, pathogenic organisms might be present. There is proof of this in cases in which after accidental injury, there is localization of these pathogenic organisms. Acute suppurative infectious osteomyelitis following slight injury or exposure was cited as an illustration of this fact. This localization is favored by certain anatomical conditions. The antagonism among micro-organisms was being considered when the time of the author expired.

In opening the discussion, Dr. Roswell Park of Buffalo, said he had done some work in this direction. He had examined pus from fifty-two sources and presented a table showing the number of cases in which pyogenic bacteria were found.

He had also prepared culture media with various antiseptics in different proportions, including carbolic acid, iodoform, iodine naphthaline, hydro-naphthol, resorcin, trichlorphenol, creolin, sulpho-carbolate of soda, boric acid, perchloride of iron, antipyrine, antifebrine and quinine. Almost the only one of these antiseptic jellies as thus prepared which has prevented all growths was hydro-naphthol, 1–100. This shows that hydro-naphthol can be relied upon as an antiseptic. Many of the bacteria grow freely on idoform jelly 1–100. Those which grew abundantly on iodoform jelly grow slightly on oxide of zinc jelly 1–100. Oxide of zinc was considered a better solid antiseptic than iodoform. The author thought that our present knowledge permitted us to associate certain bacterial forms with definite pathological lesions. In conclusion he presented the report of a case of abscess of the face in which he found the micrococcus tetragens. So far as he knew this micro-organism had never before been found in phlegmon in man.

Dr. Wm. H. Carmalt, New Haven, remarked that there was only one point to which he wished to refer; that was the alleged microbic origin of tumors. A great deal has been said in regard to the microbic origin of cancers and other tumors. He thought that the division of Virchow's class of granulomas into a class of tumors by themselves known as infectious tumors is correct. This class includes tubercle, syphiloma, lepra, lupus, actinomycosis and myelitis. These growths should be taken out of the class of tumors and assigned to a class by themselves. He had been unable to convince himself that tumors proper have a bacteriological origin.

Dr. N. Senn in concluding the discussion, said that the diseases enumerated in his paper included only those in which the specific cause had been isolated, cultivated outside of the human body, and in which the injection of this culture produced identical lesions. When these three things are done we have furnished positive proof that the disease is due to specific germs. Another class of diseases had been alluded to in the paper in which there was reason to believe from analogy that the affection was due to specific germs, although the three conditions above referred to had not as yet been fulfilled. So far no one had been able to show that the supposed bacillus of syphilis was the specific bacillus. That it is a specific disease cannot be doubted; that it is due to a microbe can not be doubted, but to establish this positively, experimenters must do what Koch did before he announced the specific origin of tuberculosis.

He was firmly convinced from his observations that tumors in the true sense of the word were not due to microbes. He had made tumor implantations for many years in animals and in justifiable cases in man both close to the original seat of disease and at remote points, without obtaining the least evidence of the *microbic origin* of disease.

Dr. W. W. Keen of Philadelphia then read a paper entitled

Three Successful Cases of Cerebral Surgery,

including 1. The removal of a large intracranial fibroma. 2. Exsection of damaged brain tissue. 3. Exsection of the Cerebral Centre for the left hand.

Case I.—Large tumor in the cerebrum probably arising from an injury at the age of three years. Tumor removed at 27. Hernia cerebri; recovery.

The patient, a young man of 27, at 3 years of age fell, striking his head on some bricks. At five he had measles, followed

by discharge from the right ear, impairing hearing. In February, 1885, epilepsy supervened, with intense pain in the head. About April, right-sided hemiplegia was complete, with aphasia. Right pupil was largely dilated and irresponsive to light. Vision imperfect.

When first examined by Dr. Keen, the only remnant of his former condition was epilepsy, hesitation of speech, and headache. In the attacks, the head and neck were turned to the left, while the body was twisted to the left. Convulsions general. Right pupil larger than left. A small scar was decided on as that resulting from the accident. This was half an inch above and in front of the left superior stephanion, 2¼ inches to the left of the middle line, and 3 inches behind the external angular process. The temperature on the left side of head was one degree (C.) higher than on the left. Dynamometer recorded, right 30°, left 35°. Left knee jerk normal, right subnormal. Diagnosis, probable tumor at the base of the frontal convolutions, involving the centres for the leg, arm, face, and speech.

The operation was performed December 15, 1887. An 1½-inch trephine was applied over the seat of the scar. This opening was enlarged to three inches. A tumor was discovered and removed. It weighed three ounces, forty-nine grains. Its size was 2⅞ inches by 2½ inches by 1¾ inches. Hemorrhage was abundant, and checked with difficulty. The wound was dressed antiseptically, drainage being provided for. The wound was followed by hernia cerebri. This showing no tendency to cicatrize, 34 skin grafts were applied. In ten weeks, cicatrization was complete. The elevation was then followed by a concavity. The tumor proved to be a fibroma—a rare form of intracranial tumor.

Case II.—Simple depressed fracture, followed in four months by epilepsy; thirteen months later trephinement and removal of damaged brain-tissue; recovery in seven days; cure of epilepsy to date.

Young man 25 years of age. In November, 1886, he fell 9 feet, receiving a severe blow on the right side of the head. Was unconscious for a considerable time. There was temporary loss of feeling in the three left ulnar fingers. On tapping the head on the right side he produced a "cracked pot" sound. Epilepsy began in March, 1887. Up to April, he had had 5 positive attacks. The diagnosis was traumatic epilepsy from depressed fracture. Centre for left hand and supra-marginal gyrus involved. Operation was done April 12, 1888. As soon as the flap was raised, the bone was found to be splintered. A 1½ inch disc of bone was removed. The dura mater had been ruptured. A small piece of bone had been forced through the dura mater and had become adherent to its under surface. The brain substance had also been ruptured. A cyst, quarter of an inch in diameter, was found connected with the piece of bone. All the brain substance that was altered in character was removed. This piece was ¼ inch long by ¾ inch in width. The button of bone was perforated and attached with chromic cat gut to the flap, so that the bone could not fall in upon the brain substance.

The wound was healed in seven days. After the operation, there was paralysis of the hand as regards flexion. That night flexion was recovered.

Note made May 28, 1888, shows that the disc of bone is adherent, mental and physical condition excellent, flexion of fingers normal. The iris of the right eye, 24 hours after the operation, responded separately as well as its fellow. This isolated symptom of want of proper reaction of the right iris, is probably a new observation, and may be valuable in the future in determining and better localizing the right centre. In this case there have been no epileptic attacks since operation. In the first case there were several attacks during the past summer.

Case III was one involving the removal the centre for the left hand and wrist. The operation was followed by recovery.

The patients were presented.

Wednesday, Sept. 19, Second Day.

MORNING SESSION.

Dr. Hunter McGuire, of Richmond, read a paper entitled

The Formation of an Artificial Urethra for Prostatic Obstruction.

It has been my lot to meet with a number of cases of hypertrophy of the prostate gland, which produce more or less obstruction to the passage of urine. These are conveniently divided into three classes.

1. Cases where the obstruction was due to temporary congestion of an already enlarged gland, which yielded to the ordinary treatment and did not return.

2. A class of cases where the obstruction to the passage of urine was permanent but

not great. Attention to the general health, the occasional introduction of the catheter and washing out the bladder were all that the cases required These cases are, however, never free from danger from exposure, etc., and gradual enlargement may go on and bring about the condition met with in the third class.

3. In these cases the obstruction is great and fixed, micturition is frequent and difficult, perhaps impossible without the aid of the catheter. The introduction of the instrument grows more and more difficult; offensive residual urine is always present and the general health suffers greatly. Cystitis, localized or general is a painful and pronounced symptom. Violent tenesmus of the bladder, provoked by the obstruction, injures the vesical ends of the ureters; possibly a reflux of stale urine is driven into these canals and ureteritis follows, then pyelitis and pyelonephrosis, from which the patient dies.

The paper was devoted to a consideration of surgical interference in this third class of cases. He was led to resort to the measures described from the following circumstances: —During the past eight months four cases of stone in the male required the supra-pubic operation. Two because of organic stricture; one because of the large size and hardness of the two calculi the bladder contained; the fourth because the stone was large and hard and the patient two anæmic to bear the shock and loss of blood which often accompanies section through the rectum.

In one of the cases of stricture in a man 65 years of age, the patient had two years before coming under obseration a second cause of obstruction. A well organized stricture was found in membranous portion of urethra. Prostate was enlarged, more marked on the left side. Urine showed no evidence of renal disease. An oxalate calculus ¾ in. in diameter was also recognized. The high operation for stone was performed. The bladder walls were found thick and unyielding, and contracted. The left side of the gland jutted into the bladder one and one half inches further than the right side. The middle lobe was of the size of the thumb and almost completely closed the urethra. It was decided to retain a fistulous opening through which urination could take place. This tract was 2½ in. long and extended upward and forward. In its passive state it was closed by the pressure of the parts through which it passed. When the bladder became full and contracted the urine was forced through the fistulous tract. He can now retain water for two or three hours, and has voluntary power both to retain and expel urine.

Case two was that of a man 69 years of age who had been cut for stone in 1881. In 1883, I found the prostate enlarged and cystitis present. He was given a gum catheter and shown how to use it. In 1886 electrolysis was employed without success in trying to reduce the size of the prostate. July 4, 1888, an operation similar to that performed in the first case was done with equally good results. At times he is able to retain urine for six hours. He never has any desire to empty the bladder no matter how full the organ is.

Mode of operation. The night before the operation the bowels are opened. On the day of operation 15 to 20 grains of quinine are administered. Antiseptic precautions are adopted throughout. The bladder is washed out with a weak solution of carbolic acid in hot water. An empty gum bag capable of holding 12 ounces is passed into the rectum. About twelve ounces of water are then introduced into it. This pushes the bladder above the pubes. The bladder is next filled with a hot solution of carbolic acid. The use of force should be avoided. The penis is tied with a piece of rubber tube to prevent escape of the fluid. A vertical incision is next made, beginning 3 or 4 inches above the pubes and extending to the symphisis. This extends to the linea alba. The incision in the latter structure should be from three-fourths to one inch shorter than that through the skin. When the transversalis fascia is reached, it should be divided, but not for more than two inches, but should reach to the pubic bone. The fat and cellular tissue between the transversalis fascia and bladder is separated with the handle of the knife. This tissue should be disturbed no more than necessary. The bladder is now drawn forward with a tenaculum and opened as low down as possible. The interior of the organ should be carefully explored with the finger.

Sutures should now be applied extending down to, but not including the recti muscles. The opening left in the skin should be at the upper extremity of the wound, so that the fistula will be oblique and from two and one-half to three and one-half inches in length. A catheter is passed through this opening. If the catheter causes annoyance it may be at once removed, otherwise it is better to allow it to remain a few hours. The dressing consists of a pledget of absorbent cotton changed

as often as necessary. In none of my operations have I met with the peritoneum.

In the after treatment it is important to keep the urine acid, for acid urine is aseptic. In operating on these cases and in the high operation for stone, the amount of blood lost has not exceeded two drachms.

Dr. John H. Packard, of Philadelphia, read a paper entitled

Supra Pubic Cystotomy.

The present paper was supplementary to one on the same subject read by Dr. Packard at the last meeting and was intended to correct an accidental omission of the views of Sir Henry Thompson. These were now considered, extensive quotations from the works of this author being given. Two cases were reported in one of which the operation was performed for the removal of a portion of silver catheter broken off in the bladder; and in the other for the removal of a piece of rubber catheter said to have been broken off several months previously. In this case a stone weighing 571 grains was removed, in the interior of which was found the foreign body.

Dr. S. W. Gross, of Philadelphia, in opening the discussion, thought that Dr. McGuire was to be congratulated on having introduced a new operation based upon the mechanism of the bladder and the physiology of micturition: the formation of a artificial urethra in a new position. The various operations which had been performed for the relieve of prostatic obstruction were next referred to, the operations of Harrison, Mercier, Bartinini and McGill were considered.

Dr. Wm. T. Briggs of Nashville, thought that perhaps in the cases reported by Dr. McGuire, a better result might have been obtained by lateral lithotomy, provided the stone were not too large to be removed by that route; for he had noted that after incision into the prostate the gland diminished in size and after the wound had healed a catheter could be passed in cases in which its use was before impossible. The perineal operation allows of freer drainage. Under some circumstances the supra-pubic operation is valuable one. This is especially the case where the stone is so large that its removal through the perineum is liable to produce serious injury of the soft parts. It is however often possible through an incision in the perineum to so break the stone as to permit its removal. Every case should be studied by itself, in some one operation is the best, in others, another is most suitable. All the circumstances of the case must be taken into consideration.

Mr. Reginald Harrison, of Liverpool, said that there are two general methods of relieving obstruction due to enlarged prostate, one by attacking the gland through the bladder and the other through the perineum. In his operation he makes a median or lateral incision through the perineum according to circumstances. The obstructing prostate is next divided with considerable freedom and a drainage tube of considerable size introduced. From this operation, he gets good results. Perineal lithotomy is preferable to the supra-pubic operation because the lateral incision gives sufficient room for all manipulations. It gives an ample opening for the removal of a stone of considerable dimensions. It also permits of the more or less permanent drainage which these cases require. He had also through a perineal opening used the perineal lithotrite with success. All methods of operation should be remembered and each employed in those cases where it seems indicated.

Professor Thomas Annandale of Edinburgh had come to the conclusion that if an operation is to be performed for the relief of prostatic obstruction, the perineal operation is the best. This allows of examination of the bladder, permits drainage and probably causes a diminution of the hypertrophy. It enables you to occasionally remove a portion of the enlarged prostate when this assumes a pedunculated form. The speaker exhibited a rubber tube which he had found useful in cases of Harrison's operation, when a permanent tube is required.

Dr. A. Vander Veer, of Albany, said that the testimony presented in his paper last year was in favor of the perineal opening so far as drainage was concerned. He had employed Harrison's operation in a number of cases and the results had been such as to impress him favorably.

Mr. Arthur Durham, of London, emphatically endorsed what had been said in regard to operation for stone, that no one operation is applicable to all cases. It is a great mistake to be men of one method, especially in surgery. When we hear a man say that he treats all his cases of fracture in such a way, all his cases of stone in such a way and all his cases of prostatic disease in such a way, we may be sure that such a man has a very small practice and experience, or else is a very great fool. In cases in which stone in the bladder is complicated with enlarged prostate, the perineal incision

seems to me to be better than the supra-pubic. He described a method of performing perineal lithotomy which is performed with satisfaction at Guy's Hospital. This consists in the use of a straight staff, the groove extending to within one-third of an inch of its extremity. A knife with a straight back is passed through the perineum until it reaches the groove, then carried along the groove to its extremity and, the point of the knife being held in close contact with the staff, the two are carried forward into the bladder, thus avoiding many of the risks of the operation as ordinarily performed. In concluding, he referred to the great improvement of the Bigelow operation over the old method of crushing for stone. He had no doubt that this method renders both lateral and supra-pubic lithotomy much more rare than they have been in the past.

Prof. Hingston, of Montreal, believed that the supra-pubic operation was one to be performed only in exceptional cases. These he classified as follows. 1. In those cases of stricture in which the obstruction can not be overcome in time to relieve the patient of great suffering. 2. In cases of prostatic obstruction. 3. In cases of tumors of the bladder which would interfere with the lateral operation. 4. In cases where the stone is too hard or too large to be removed either by lithotrity or by lateral lithotomy. He had himself removed without injury to the soft parts, a stone weighing five ounces and five drachms.

Sir Wm. MacCormac, of London, had performed the operation of supra-pubic cystotomy occasionally. He had never seen any untoward consequences and the operation seemed to be devoid of all risk. He did not consider that drainage was necessary after this operation. The bladder empties itself freely and the drainage tube is a source of irritation.

Dr. Hunter McGuire said that the only object of his paper was to describe the two cases in which he had made an artificial urethra to relieve prostatic obstruction. The various operations referred to were not applicable to all cases, while the formation of an artificial urethra could be done in all cases. He was surprised to hear that supra-pubic cystotomy was considered dangerous. It had the advantage of avoiding some of the unpleasant consequences of the lateral operation, such as dribbling of urine and impotence.

Dr. J. H. Packard did not want to be considered as an advocate of supra-pubic cystotomy. It had however been shown that the dangers attributed to this operation, did not exist. He considered that the operation was a valuable resource in certain cases. After this operation he had noted diminution in the size of the enlarged prostate. This he attributed to the rest afforded the bladder. It will take place in whatever way the rest may be obtained.

The President, Dr. D. Hayes Agnew, being called upon, said the ground had been so thoroughly covered that there was little to be added. He agreed with those who held that no single operation was applicable to all cases. The supra-pubic operation may be appropriate in certain cases, while in others the perineal operation is the proper one. In order to avoid the unpleasant consequence which occasionally follow the perineal operation in children where the prostate is small, I avoid the introduction of the finger into the bladder and remove the stone with forceps not much larger than the staff.

While there may be no danger in the supra-pubic operation in skilled hands, yet with the inexperienced operator there will be risk of opening the peritoneal cavity. He thought that a number of cases had been reported of rupture of the bladder following injection of the organ after dilatation of the rectum with the rubber bag.

A paper entitled

Forty Years of Chloroform and Ether in Louisville, Ky.,

by Dr. D. W. Yandell, of Louisville, was read by title.

The following are the officers of the Association for the following year: *President*, Dr. D. W. Cheever, of Boston; *Vice-Presidents*, Dr. T. W. Richardson of New Orleans and Dr. John B. Roberts, of Phila.; *Secretary*, Dr. J. R. Weist, Richmond, Ind.; *Treasurer*, Dr. P. S. Conner of Cincinnati; *Recorder*, Dr. J. Ewing Mears, Phila.; additional members of Council, Dr. W. F. Peck of Davenport and Dr. S. W. Gross of Phila.

The next meeting to be held, beginning the second Tuesday of May 1889, in Washington. Chairman of Committee of Arrangements, Dr. J. S. Billings. Member of Committee of Arrangements, Dr. J. Ford Thompson of Washington.

AFTERNOON SESSION.

Dr. W. T. Bull, New York, read a paper entitled

The Surgical Management of Typhlitis and Perityphlitis.

The author reported seventeen cases oper-

ated on by himself. These he divided into three groups. The first included ten cases in which abscess was opened by incision without opening the general peritoneal cavity, at periods varying from seven days up to six weeks from the beginning of the attack. All of these cases recovered; the second group included six cases in which laparotomy was performed seven times for supposed perforation (one patient being operated on twice). The earliest operation was at the expiration of 36 hours, the latest on the fifth day. Death occurred in two of these cases, one from incomplete operation and the other from imperfect technique; the third group contained but one case, but the author hoped that in the future more would be reported. In this case laparotomy was performed in the presence of threatening symptoms, on the twelfth day, of an attack of perityphilitis. No pus was found and no signs of recent peritonitis. The appendix was surrounded by old adhesions. The diagnosis of this class of affections was then referred to.

The operations described were laparotomy and simple incision of the abscess. Antiseptic precautions should be adopted in both. The incision for laparotomy should begin a finger's-breadth above the right Poupart's ligament and extend upward four inches. The peritoneum should be divided at the lower angle of the wound. Adhesions are then separated and any pus found, evacuated. The intestines should not be allowed to escape through the wound. The region behind the cæcum must be carefully examined. If there is perforation or gangrene of the appendix it should be removed at its junction with the cæcum. After thorough washing out of the cavity a drainage tube should be introduced, passing to the bottom of the iliac fossa.

For opening an abscess, the incision should start from the point before mentioned and continue either parallel with the ligament or more vertical, according to the position of the abscess. Incision may be required above and parallel with the crest of the ilium if the maximum of tumefaction is found there.

A brief report of the cases operated upon was then given, and the following conclusions presented:

Our present knowledge justifies the statement that both the cæcum and appendix may be the starting point of an inflammation spreading to the peritoneum or to the peritoneum and cellular tissue of the illiac fossa, constituting a complicated lesion which for convenience sake we may call "perityphilitis."

This may be, in its clinical course, resolving or suppurative, each marked by definite symptoms in some cases; in others difficult to recognize.

Needle-exploration is a justifiable and desirable method of diagnosis, though attended by some risks. These may be reduced to a minimum if care be taken to reserve the practice for cases where the symptoms have lasted several days, and where a distinct indication "tumor" can be made out.

Suppurative perityphilitis may be a spreading or limited (circumscribed) peritonitis. Both begin with the same set of symptoms, and it is important to discriminate between them in the first 24 or 48 hours or even on the third day.

The presence of any of the local or constitutional signs of general peritonitis justifies the diagnosis of a spreading or generalization, and calls for the performance of laparotomy and the repair of the lesions found.

The absence of these signs or their strict localization warrants delay of a varying length. Any time after a week the abscess may be opened by an incision which must reach the pus, whether it be extra- or intra-peritoneal.

In doubtful cases, the risk of the operation is less than the risk of the disease.

The propriety of exploring and removing the appendix in recurring cases must still remain *sub judice*.

Dr. J. Ewing Mears, of Philadelphia, read a paper entitled

The Propriety of Surgical Interference in Perforating Typhoid Ulcer.

The present state of our knowledge and our largely accumulated experience have enabled us to define, with a degree of exactness, the limits of surgical interference in certain affections of the abdominal organs. The researches of Senn have shown that complete extirpation of the pancreas is invariably followed by death, while partial excision is a feasable operation. We are also able to define the limits of operation in affections of the spleen and kidneys. We may venture to approach the discussion of operative interference in perforating typhoid ulcer with the feeling that here we may be compelled to define a limit to the employment of surgical measures, not without regret at our inability to overcome the

barriers which oppose success, but with a desire to maintain always the good repute of surgical science and art.

A clear distinction must be made between the widely different conditions which precede and follow perforation in typhoid ulcer and in ulcerations of the intestinal canal due to other causes. In typhoid fever, in addition to the intestinal lesions, there is a general degenerative process involving all the important organs. In traumatism, the general condition of the patient may be good. In inflammatory conditions, while the general system may be profoundly impressed, the lesion may be regarded as local in its nature. In diseases of a chronic character, the system has accommodated itself to the impression made by the morbid affection, and the degenerative changes which may occur are not usually general in character.

The symptoms are usually quite distinctive. Death, as a rule, occurs on the second or third day; rarely the fatal result may be postponed two or three weeks, and instances are recorded in which recovery has taken place, adhesions having occurred between the edges of the perforation and adjacent parts.

A careful search of current medical literature reveals but four cases of surgical interference in perforating typhoid ulcer, in all of which a fatal result occurred. The reports of these four cases were given in detail. These cases were operated on by the following surgeons: Prof. Kussmaul, of Strasbourg, Mr. T. H. Bartlett, of Birmingham, Dr. R. B. Bontecou, of Troy, N. Y., and Dr. T. G. Morton, of Philadelphia. In Prof. Kussmaul's case the disease was severe and perforation occurred early when the infectious process was at its greatest height and the vital forces at the lowest point. In Dr. Morton's case the disease was mild, "a walking case." In both of these cases the shock consequent upon the perforation was prompt and profound. In the first case operation was performed within a few hours, but death without reaction from shock occurred in eleven hours. In Dr. Morton's case operation was resorted to twenty hours after the accident. Six hours after operation, the patient sank into a collapsed condition and died. The operations in these cases were performed by surgeons of experience, under strict antiseptic precautions and within a reasonably short time after the accident. We must therefore look for the cause of failure in the systemic condition; the degenerated and devitalized condition of the organs and tissues caused by the infectious process in active progress, utterly deprived of the power to resist the shock of operation; or in the condition of these structures beginning to recover from the effect of the poison in milder form, extremely sensitive to any rude impressions and wanting in tone and power of resistance. It is in the latter conditions alone that the surgeon may hope to achieve success by surgical interference, and then only when such methods are adopted as will reduce to the lowest point the shock of operation.

The following propositions and suggestions were offered: 1. Surgical interference is not justifiable and should not be instituted in cases of typhoid fever in which perforation occurs when the infective process is at its height. 2. In mild cases of the disease in which the pyrexia has not been of high grade, and in which perforation occurs at the end of the third week, or later when the stage of convalescence is fully pronounced, laparotomy may be performed. Surgical interference in cases of this character is advocated with the hope that if the method of operation suggested by Lücke—laparotomy with the creation of an artificial anus—be adhered to, success may be attained. 3. Rapidity of operation will be an essential factor in the achievement of success—through which prolonged exposure of the cavity will be avoided and shock greatly lessened.

Dr. B. A Watson, of Jersey City, in opening the discussion, said that, in cases where perforation has occurred the sooner operation is performed the better. He considered that it is safer to make an exploratory incision than to use the needle. In regard to the paper of Dr. Mears, it covered the ground completely. In those severe cases of typhoid fever where perforation occurs and life is about ebbing away, it would be folly to resort to operation, but in mild cases where perforation occurs the operation should be done early.

Dr. R. B. Bontecou, of Troy, N. Y., had performed the operation in one case of perforation in the third week of typhoid fever; the patient, however, died. He thought that it would succeed in some cases, as in those in which perforation follows imprudence during convalescence.

Dr. O. B. Nancrede, of Philadelphia, thought that the proper place for incision was two inches to the right of the anterior superior iliac spine. He had operated in two cases; in the first there was no pus, but three or four perforations were found. This

patient recovered. The second case was that of a child operated on four days ago. The patient had done well since the operation.

Dr. Gordon, of Portland, referred to the absence of symptoms met with in these cases, and cited a case in which the symptoms were not distinct but in which a pint of pus was found, with general peritonitis and perforation of the appendix. In this case an incision on the right side would not have reached the pus.

Dr. D. W. Cheever, of Boston, reported a case in which strangulation of an old hernia occurred in the third week of typhoid fever, the patient not being seriously ill. A simple incision through the sac was made and the bowel replaced, but the patient did not rally from the shock.

Dr. W. H. Carmalt, of New Haven, referred to a case which had come under his observation with symptoms of internal obstruction. Operation was suggested but refused. The patient died and the autopsy showed perforation of the appendix, extravasation of fæcal matter. The appendix was attached deep down in the pelvis where there was a small collection of pus. This was reached only with the greatest difficulty and after turning the intestines out of the abdominal cavity. This abscess was unaccessible to any of the ordinary methods of operation. The careful exploration of the rectum in this case failed to reveal any sign of disease.

Dr. Joseph Ransohoff, of Cincinnati, thought that the general impression that perityphilitis is necessarily associated with perforation, was an error. There are two classes of cases. In one there is a distinct tumor and in these early operation is by no means indicated. In these cases adhesions have formed and there is a natural tendency to cure. In these cases the abscess finally perforates the abdominal wall or is relieved by incision. The second class is that in which the symptoms of perforation develope suddenly. In these cases the incision should be median.

Dr. T. F. Prewitt, of St. Louis, thought that there must be many cases of inflammation in the region of the cæcum that never suppurate. He recalled a number of these cases, only two of which had died, one from perforation and the other an old man from exhaustion incident to an intestinal affection. In almost all of these cases the patients had had three or four previous attacks.

Dr. Reginald H. Fitz, of Boston, held that the appendix was the seat of disease in the great majority of cases. The symptoms usually enabled the physician to make a correct diagnosis. The use of the exploring needle was not considered advisable. The cæcum can always be readily found by remembering that it is attached to the colon.

Dr. George W. Gay, of Boston, remarked that in the cases on which he had operated, recovery had followed in those cases in which offensive pus had been evacuated, while in those where he had found only serum and flakes of lymph, a fatal resulted followed operation.

Dr. John H. Packard, of Philadelphia, read a paper on

Simultaneous Ligation of the Right Carotid and Subclavian Arteries for Aneurism of the Innominate.

The symptoms of aneurism followed a blow upon the chest. The patient died three days after the operation with symptoms of suffocation. No autopsy could be obtained.

[to be continued.]

Hospital Notes.

Hospital of the University of Pennsylvania.

Reported by Henry W. Cattell, A.M., M.D., Assistant Demonstrator of Chemistry, University of Pennsylvania.

Amputation of Thigh for Giant-celled Sarcoma.

Prof. John Ashhurst, of the University of Pennsylvania, introduced Prof. von Esmarch as his clinic Sept. 22, 1888, as occupying the Chair of Surgery at the University of Kiel, and one of the most distinguished of German Surgeons.

The Professor is a venerable looking man and to him and Silvestri belong the honor of first using what is known as the Esmarch bandage or apparatus for bloodless operations. The professor speaks English with a perfect accent but is at loss now and then for a word. He began by saying:

"While I am relating the history of the patient I always prepare my hands by washing them antiseptically; this saves the time of cleansing them beforehand and then as the hands are washed at the last moment one is sure that they are thoroughly aseptic. The patient that is to be operated on to-day is a woman suffering with a large growth involving the left knee. This growth has

grown within the last eight months and is no doubt a giant-celled sarcoma and will require an amputation of the thigh. I prefer to perform the circular amputation by a single incision. I will now apply the bandage and tourniquet, but will only apply the bandage up to the knee, or otherwise, by the pressure some of the giant cells might be driven into the circulation and the disease be propagated in this manner. I use the elastic bandage which I described many years ago for thigh amputations. The bandage is applied so as to retain as much blood as possible in the body."

The Doctor used a broad bandage of about two inches in width for the tourniquet instead of the narrow tubing generally used in this country. It took twelve seconds for him to make the circular incision, 40 seconds to free the flesh from the bone, and thirteen seconds more to saw the bone—the amputation thus occupying a little over one minute, the seat chosen being the middle third of the thigh. While the vessels were being tied by Drs. Ashhurst and Wharton, the Doctor made a dissection of the tumor and said:

"We find here many cysts and much extravasated blood, both of which are very common in a giant-celled sarcoma. Part of the bone has become the walls of the cysts. The growth probably started in the inferior part of the femur and has completely destroyed the articulation and has also involved the upper part of the tibia. The thigh is broken just above the knee, as we can easily see by the great freedom of motion. We will now dissect the patella and lay it back, as in this manner the arrangement of the growth can most plainly be seen. I have had very many cases of this kind in which I have operated as I have done in this patient, and there has been no return of the disease. In some cases it is possible to amputate with the loss of only a teaspoonful of blood, but in the present case the vessels are all much enlarged and so we have had more bleeding than usual. I generally allow the tourniquet to remain on for five or six hours after the operation; but, of course, ligate the vessels and dress the part at once. Catgut ligatures are used. The periosteum is ligated as well as the sartorius muscle which, unless this be done, is liable to contract. I do not use a drainage tube but allow the angles of the wound to remain open, and at the end of four weeks they will usually be found nearly healed. I use 1 to 10 carbolic acid solution for the instruments except the knife, which is laid in alcohol. For washing the wound I use 1 to 5000 bichloride, as I have found that a 1 to 2000 solution will cause an eczema where the dressing comes in contact with the skin. I dress with sterilized gauze and gauze dipped in the bichloride solution. Wire, or preferably, catgut may be used for sutures. A little compression is used in applying the bandage, and I use a cushion of moss in place of cotton as it is more elastic and cheaper. I do not find it necessary to remove the first dressing for three or four weeks unless there be a rise of temperature, when the dressing is at once removed. Thanking you for your kind attention I will now say good-bye."

Examination of the Heart.

Dr. Pepper at his clinic on September 22, introduced Dr. Sansom, of London, the celebrated specialist on heart diseases, and asked him to show the students how he would make an examination of a patient while making his rounds in the London Hospital.

In making the examination of a patient suffering from heart disease the following method was employed:

A camel's hair brush, some olive oil, a pencil, or still better, a dermatograph, a plexímeter, a binaural and single-stethoscope are required. The plexímeter is **T** shaped, about one and a half inches in height, and made of hard rubber or glass. It is held to the chest with the index and middle fingers of the left hand and tapped with the middle finger of the right. The usual methods of investigation viz., inspection, palpation, percussion and auscultation are employed in the physical examination of the heart. The walls of the heart are outlined with the plexímeter and marked with the dermatograph. Percussion is then made just within the line where dulness is to be expected and just without the line where resonance is to be found. If any mistake has been made it is clearly demonstrated and the line can easily be corrected. The apex beat is located and marked A; other points of interest observed are marked with arbitrary letters. The lines are then moistened with olive oil, the sternal notch, clavicle and ribs being also touched with the oil; and a piece of ordinary copying paper is placed over the chest and gentle pressure is applied. The marks of the dermatograph together with the outline of the sternal notch, clavicle and ribs are thus accurately and completely transferred to the copying paper. The name and date are added and the paper is ready for future reference.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PHYSICIANS AS WITNESSES.

From time to time interesting questions arise in regard to the rights and duties of physicians when summoned as witnesses in a court of law, and unfortunately the status of physicians as witnesses is not clearly defined, or it is very imperfectly understood, in the United States. This is the more to be regretted, because it sometimes leads to contentions which are annoying to the courts and prejudicial to the standing of physicians in the community. A case in point has very recently occurred in Wilkes Barre, Pa., where a physician, being summoned by the Coroner to testify in regard to the circumstances attending the death of a woman who died when under his care, refused to present himself at the inquest because his witness-fee was not guaranteed or paid in advance, until an attachment was served upon him, and then declined to answer the question: "What were Mrs. Duningan's symptoms when you were first called to attend her?"

In a letter, which the physician in question was kind enough to write to the Editor of the REPORTER, in response to a request for information, he states that his reason for declining to answer this question was that the "reply required professional skill"; and to the Coroner he stated that he declined to answer as a physician before the witness-fees were paid or guaranteed.

The information which we have in regard to this case leads us to feel a great deal of sympathy with the physician, who seems to have suffered on previous occasions when he gave testimony, trusting that his fees would be paid afterward. We heartily wish that courts and persons exercising the right of summoning witnesses, would provide a proper remuneration for medical men who are called away from their professional duties to act as witnesses, and that the remuneration were always promptly paid. This is a simple question of justice, and all sensible men can agree in regard to it.

In a civil case a witness may, indeed, refuse to attend at the trial, unless his traveling expenses and at least one day's pay for attendance are tendered him. But the rule is different in criminal cases, because the Government has the right to call any citizen to testify, and he must go when called. The Government is both legally and morally bound to pay him finally, but the question of pay is a separate and distinct one, which does not affect the duty of a citizen to obey the summons of a court. These statements, as we have the best authority for saying, apply also to the subpœna of a Coroner.

But the Wilkes-Barre case involves another point. The position of the physician in refusing to testify, in this case, rests upon two assumptions: one, that an answer to a question in regard to the symptoms of his patient would place him in the category of "expert"

witnesses; and, the other that an expert witness has the right to demand payment for services differing from that accorded to ordinary witnesses.

The first assumption, we are sorry to say, we think is wrong; and we have little doubt that a court would decide that the use of the technical word "symptoms," in the question, was simply a convenient way of asking for facts which had been observed by the physician, and which he had no right to withhold, merely because his education fitted him to observe them intelligently and to describe them intelligibly. If this were not the case, we might imagine a mechanical engineer refusing to testify as to the behavior of an engine before it burst, or a civil engineer as to the appearance of a bridge shortly before it gave way. Courts of law have the right to summon the most competent witnesses of any occurrence under investigation; and special fitness to observe and describe these occurrences does not relieve any one from the duty of testifying all his knowledge of them.

The second assumption: that a witness, when asked a question, the correct answering of which requires peculiar knowledge, becomes an "expert witness," and has a right to demand treatment—especially in regard to remuneration—different from that accorded to witnesses in general, is one which we wish was tenable.

In the case of medical men, it ought to be true that, when called upon to testify in regard to matters requiring strictly professional skill, they would receive consideration suited to the position in which they are placed, and remuneration appropriate to the amount of special preparation required for instructing the court. But, as the law now stands, there is no provision for "expert" witnesses, and experts cannot secure any other than ordinary witness-fees, unless they are paid by the parties to any litigation. We may not like it; but this is the fact.

As the matter stands now, a physician who is summoned as a witness has no rights above any other kind of witness. When subpœnaed he must attend, and when questioned he must answer, unless, on appeal to the court, he is excused from answering. This fact should be known to all medical men, so that they may not assume a position which is sometimes annoying and irritating to the officers of justice, and which may prove embarrassing or dangerous to themselves.

Our sympathy is naturally with our professional brethren in regard to their position when called as witnesses. We know how trying this position often is. But we are fully convinced that no good can come of following our feelings against the law and the settled custom of the courts. The only way in which the position of medical witnesses in the United States can be improved is by appealing to the legislatures to define this position in a way more consistent with our ideas of what is right. Men who take the stand taken by the Wilkes-Barre physician may, by making martyrs of themselves, as some men have done, and as he seems willing to do, draw attention to the subject in a way which will result in changing the present treatment of medical witnesses; but at present it must be admitted, if we would not deceive ourselves, that the law does not recognize any class of witnesses that can make terms with a court, or refuse to attend or decline to testify when summoned in the ordinary way.

DR. WILLARD H. MORSE.

In the *Druggists Circular* for September, 1888, there was a long and circumstantial account of the arrest of Dr. Willard H. Morse, of Westfield, N. J., on the charge of using the U. S. mails for a fraudulent purpose. The article described how a trap was set to catch Dr. Morse, by getting him to make a false certificate of a chemical analysis of a certain commercial article, and how he seemed to fall in it. His arrest was accom-

plished throught the instrumentality of the well known Mr. Anthony Comstock. As it was first reported,—and the story was extensively published in the daily papers—the case seemed to be hard against Dr. Morse. As the latter has been a contributor to the columns of the REPORTER, an article of his appearing as late as September 1, 1888, we felt a natural interest in his case, and were glad to receive from him a letter, in which he assured us that the charge against him was false and that on Monday, Sept. 10, he was honorably acquitted, before U. S. Commissioner Keasbey, of Newark, and that the latter, and Mr. Comstock, and the Editors of the Druggists Circular were satisfied that he was innocent.

On receiving this letter, we wrote to the editors of the Druggists Circular, to ask if they were correctly reported. In reply, they wrote that the claim made to us by Dr. Morse was "false from beginning to end." This plain statement has been followed up by the publication in the *Druggists Circular* for October of a full account of the proceedings against Dr. Morse, and their issue. The result, according to this account, was very far from an honorable acquittal, and we regret to say that it leaves us under the impression that Dr. Morse fell into a trap which would not have caught an honest man.

We refer to this matter partly because our readers have a right to know when one who has been allowed to use the columns of the REPORTER seems unworthy of confidence, and partly because Dr. Morse has had the assurance to ask us to vindicate him to the readers of this journal. We think we deal fairly with him and our readers when we say that he now occupies a position which has every appearance of being that of an unscrupulous and dishonest man. If this is the result of misfortune, we are very sorry for him; if it is the result of deliberate wrong doing, we trust his present shame may direct him into more honorable paths in the future.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION AND THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

It is with some regret that we note the fact that the number of the *Journal of the American Medical Association* for September 22 contains a letter from an anonymous correspondent in London who speaks in terms of severe disparagement of the recent Congress of American Physicians and Surgeons, which has been so great a success and so creditable to the profession of this country. The Editor of the *Journal* might have spared his countrymen the bitterness and malevolence of this unjustifiable affront, and his error in laying it before the readers of the *Journal* is the more unfortunate in view of the paragraph which immediately followed it.

The *Journal of the American Medical Association* was not intended to be the organ of any man, or of any party, and the best friends of the Association cannot be pleased when it is used to pay off old grudges or to gratify personal vanity.

It is a pity that such an unpleasant thing should have to be said; but the occasion seems to call for it. The part of the letter to which we have referred is published in another place in this number of the REPORTER, and our readers may judge for themselves whether or not our strictures upon it are justifiable. We have little doubt, however, that the charges of dishonorable conduct made by this anonymous correspondent will be repelled with equal indignation on both sides of the Atlantic, and that it will be fortunate for his reputation if he succeeds in concealing his personality.

THE QUARTERLY COMPENDIUM OF MEDICAL SCIENCE.

We desire to call the attention of the readers of the REPORTER to the quarterly magazine published at this office. It is not a duplicate of the REPORTER, but an inde-

pendent publication, which contains select papers taken from other medical journals—chiefly of Europe—and translations, classified according to subjects, and carefully edited. It makes a summary of the progress of medicine for each year, and includes papers which are rather too long for quoting in the REPORTER, or for which we have no room in this journal.

It is impossible, in the REPORTER alone, to give our readers all the medical news we would like to, and the best we can do is to offer them, at a very low price, this supplement, which consists of four numbers a year, each containing about 150 large octavo pages handsomely printed and covered, and which is worth more than many books of the same size which are sold at a higher price.

We are just now sending out specimens to those of our subscribers who do not take the COMPENDIUM. In doing this we are sending as many as we can of the latest issues; but last year's issue is worth the price and whoever gets a copy of it may be sure that this year's is, and next year's will be, every way better. We hope to hear from many of our readers, and to have a large addition to the subscription list of the Quarterly Compendium.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION. Part Third; Medical Volume.

With this volume the United States Government brings to an end the unparalleled series of books, published under its authority, describing the medical and surgical experiences of the army of the United States during the civil war. Those who are familiar with the volumes which have preceded this one will understand that it is praised sufficiently when we say that it is a worthy successor to them. Its text is most judiciously arranged, and its illustrations are simply superb. It is a monument of the munificence of the Government, and of the skill and devotion of the Surgeons of the Army.

The labor involved in preparing and issuing such a work as this can never be fully appreciated by those who have not been engaged in it; but all can admire the result, and pay their tribute of respect to the industry and genius which have combined to produce a work which sheds so much lustre upon the medical department of the United States Army.

A CLINICAL ATLAS OF VENEREAL AND SKIN DISEASES. BY ROBERT W. TAYLOR, A.M., M.D., Surgeon to Charity Hospital, New York, etc. Parts I and II. Philadelphia: Lea Brothers & Co., 1888. Price $2.50, each part.

This magnificent work which is to be completed in eight parts contains a large number of handsome colored plates representing a variety of conditions of the genitalia caused by venereal disease. Fortunately for mankind such appearances as are here shown are rarely seen outside of hospitals devoted to the care of the outcast or impoverished classes. Still, every student of venereal diseases ought to be familiar with them, and to those who have had the benefit of hospital experience or observation which included such sights as this work represents, its plates will serve as a powerful reminder of what they have seen before, while those who have had no such observation will find here uncommonly graphic and faithful representations of them.

In a work of this sort the text must be, to a certain extent, subordinated to the pictures. Its methods are more like those of the clinic than those of the lecture-room. But it is none the less instructive for this fact, and on this very account it is more interesting than a formal treatise could be. The reputation of the author as a syphilographer assures the reader that he may trust the scientific statements it contains, and the artistic excellence of the plates speaks for itself.

THERAPEUTICS: ITS PRINCIPLES AND PRACTICE. BY H. C. WOOD, M.D., LL.D., Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System in the University of Pennsylvania. Seventh edition. 8vo, pp. 908. Philadelphia: J. B. Lippincott Co., 1888. Price: cloth, $6 00; sheep, $6 50.

When Dr. Wood first issued his work on Therapeutics it immediately took a very high rank in the estimation of the profession, and this rank has been maintained as it has passed through its various editions, until now there is little need for praising what is already so well known. No work in the English language contains so complete an account of the physiological action of drugs, and none contains a more intelligent account of the way in which drugs should be used.

This last edition has all the merits of its predecessors, and more. It has been thoroughly revised so that it includes the most recent additions to the list of medicaments, and it has been rearranged so as to make its information more easily accessible to active practitioners. We can heartily recommend it to the notice of our readers, and congratulate the author upon its contents, and the publishers upon the way in which it is issued from the press.

THE APPLIED ANATOMY OF THE NERVOUS SYSTEM. BY AMBROSE L. RANNEY, A.M., M.D., Professor of the Anatomy and Physiology of the Nervous System in the New York Post-Graduate Medical School and Hospital, etc. Second edition. 8vo, pp. xxxv, 791. New York: D. Appleton & Co., 1888. Price $5.00.

Dr. Ranney's book gives a very complete description of the different parts of the brain, spinal cord

and nerves, both in regard to their anatomy and physiology and in regard to their various pathological conditions. The portion of his work devoted to cerebral localization, and to the course of the different nerve tracts in the cord and brain, are especially full and instructive. A work of this kind is a necessary part of the library of every neurologist, and would be a valuable addition to any library. Nowadays the work of the surgeon is so often applied to the treatment of diseases of the nerves and spinal cord and brain that surgeons need to know a great deal which was once considered to be entirely within the province of the neurologists. To such surgeons as appreciate this need we can heartily recommend Dr. Ranney's book, the text of which is clear and intelligible, and the illustrations of which are admirable.

Finally, it may be stated that the book is very handsomely printed and well bound, and that it reflects as great credit upon the publishers as upon the author.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

Memoir of A. F. Erich. By George H. Rohé, M.D., Baltimore, Md. 15 pages. 1888.

On the Treatment of Acute Rheumatism, with Special Reference to the Use of the Salicylates. By Donald W. C. Hood, M.D., London, England. 66 pages.

—Dr. Rohé, at the request of the Faculty of the College of Physicians and Surgeons of Baltimore, prepared this Memorial Address on the life and labors of his fellow-professor Dr. A. F. Erich. Its style is admirable, and it presents a sketch of Dr. Erich's life worthy of the careful attention of all who admire what is excellent. As the tribute of a friend it is full of warmth, and as a study of character it is marked by great discrimination and judgment.

—Dr. Hood's pamphlet, to which we have already called attention in an editorial in the Reporter, May 26, 1888, contains a most elaborate and interesting study of the treatment of acute rheumatism, and especially of the effects of the salicylate of soda. He is a strong advocate of the use of this drug in acute rheumatism; but he is a discreet and temperate advocate, who discriminates between the different conditions which different cases may present. It would be of advantage to all thoughtful medical men to learn what Dr. Hood has to say on the subject he here discusses; for there is much in his paper beside the mere study on therapeutics indicated by its title.

—Dr. William Osler, Professor of Clinical Medicine in the University of Pennsylvania, has been appointed Physician to the Johns Hopkins Hospital, and Professor of Medicine in the Johns Hopkins University, Baltimore. Dr. Osler took his degree in McGill University, Montreal. He subsequently studied in London, Berlin and Vienna, and in 1885 was appointed Gulstonian Lecturer for that year before the Royal College of Physicians, London; and in 1886 he delivered the Cartwright Lectures in New York.

Correspondence.

The Toxicity of Fruit Juices.

To the Editor.

Sir: In these days when we are told that poisonous germs are concealed in every gutter when we are abroad; when in a room in our own homes the air may be freighted from a badly constructed system of drainage or by overcrowded rooms; and when, even in the country, we may be drinking impure water from a sparkling spring—I say, when we have these and many other just causes for true alarm, it is little less than a sin to trifle with people's credulity or resort to unfair means to advertise one's self by misrepresentation. No class of people is more open to criticism than is the apothecary. He is attacked on one side by those who say he adulterates; on the other by those who think he charges them exorbitant prices. The latest specimen of the former class is the "Toxicity of Fruit Juices" crank, who insists that nearly all the syrups the thousands of people in this country are daily consuming are artificial, and that those who use them are not only wilfully cheated, but also given poisons which are calculated to impair their very vitality by slow degrees. This charge is a base slander; and one must be a fool to think the majority of people would believe it. The better class of drug stores all over the country use natural fruit juices: just as the better confectioners flavor their goods with natural fruit juices or extracts made from them. Almost any one can distinguish an artificial fruit juice from a natural one, and I venture to say there is not one drug store in fifty—taken promiscuously—that would sell artificial syrups. While an apprentice in the drug business, and within a few years after, I was in seven different stores, two of these at the seashore, and during that time I have handled hundreds of gallons of fruit juices, and I have never sold a single artificial fruit syrup nor heard of a respectable druggist who has done so.

A great many apothecaries express their own juices, while the majority buy them of reputable manufacturers, who make them on a large scale more cheaply than they can be made in a small way. So great has this industry become within the last few years that these manufacturers contract a long time ahead to take a fruit-grower's whole crop; and any one who will take the trouble to look the matter up can easily be convinced of the great amount of fruit used for this purpose.

Why any man should make such false charges as were made in an article on the Toxicity of Fruit Juices, in the REPORTER, Sept. 1, p. 267, 1888, is beyond my power to understand. If he has erred from ignorance, I hope you will use this means to correct his false statement; if he has deliberately stated what he knew to be untrue in order to advertise a very "shaky" means of existing—that of pretending to be an analyst, when he has no right to the name—it is high time that his pretensions were exposed, and he himself shown in his true light, whatever it may be.

Yours truly,

Philadelphia, September 29, 1888. CORNELIUS W. STRYKER.

NOTES AND COMMENTS.

Carping Criticism.

The *Journal of the American Medical Association*, Sept. 22, contains an unsigned letter from an "occasional correspondent" in London, which concludes as follows:—"The meeting this month, in Washington, of the Congress of American Physicians and Surgeons, has made little or no impression upon the mass of medical men throughout Europe. Now and then I have heard reference made to the meeting in a kindly manner in this and other medical centres. A very large number of eminent members of the profession in all parts of Europe have been invited, and even urged, to attend, and but few, very few, will be at the meeting, even though, I am told, *suggestions have been made to many that possibly American degrees may be conferred upon many who will honor them by their presence.* [Italics ours.] Unfortunately for the present managers of the Congress, the part they have taken during the past year against their own countrymen has now become more apparent here, and the reaction has been anything but favorable to them and their meeting. The suggestion, or even the promise, of degrees to be given out, which is whispered around here, may induce a few to attend the meeting, but the very many invited will stay at home.

"I cannot close this brief letter without making reference to the second visit to the late meeting of the British Medical Association, of the Father of the American Medical Association. Dr. Davis was received not only warmly, but enthusiastically, and all honor was shown the late President of the Ninth International Medical Congress."

Irish Lunatic Asylums.

From the thirty-seventh annual report recently issued, it appears that at the close of last year the insane in Ireland had increased by 561 as compared with the preceding year. This increase occurred among the lunatics in public asylums, poorhouses, and in private institutions, and is considerably more than in any previous like period. The admissions into district asylums for the year numbered 2863, which, with those previously admitted, make a total of 12,940 under treatment, of whom no less than 620 were relapsed cases, some for a fourth and fifth time, and not a few at regular intervals—facts indicative of the recurrence of mental disease. Of these 12,940 inmates, 1582 were discharged; of whom 1123 had recovered, 375 were relieved, and in 84 instances no improvement had taken place. The mortality amounted to 857, or a death-rate of not quite 7 per cent. on the total treated.

With respect to the curative and beneficial results of treatment during last year, the former, if compared with admissions alone, would show a return of nearly 40 per cent.; but on the average under treatment, the cures would stand at about 11 per cent., and the improved at nearly 4 per cent. As regards the relative proportion of the probably curable to the incurable, they stand in the ratio of 1880 of the former to 8619 of the latter, in which are included, to the number of 827, epileptics, lunatics, and idiots. The average capitation cost on the daily average of inmates amounted to about one hundred dollars.—*Lancet*, August 18, 1888.

Antimony in Acute Rheumatism.

For acute rheumatism, so long as it affects the joints only, Professor Jaccoud (*Journal de Médecine de Paris*, May 6, 1888) is quite satisfied with the treatment with salicylate of sodium. But when the pain has gone, and nevertheless maintenance of the high temperature or the development of hyperpyrexia shows some complication at work, he thinks the use of the salicylate of no avail or even harmful, and resorts to a treatment by a depressant, viz., tartar emetic, pushed to an amount which produces vomiting. In cases which occupy an intermediate position—in which under the salicylate treatment the pain ceases, but the temperature is only slightly reduced—he employs hydrobromate of quinine in doses of about four grains every six hours. —*Practitioner*, July, 1888.

Honors for Women Doctors.

The French Government has just distinguished itself by conferring the officership of the Academy on Madame Gaches-Sarrante, the doctor to the Grand Opera of Paris, for "exceptional services." What the exceptional services consisted in we are not told, but the woman's career is one worth noting as an instance of what indomitable perseverance, assisted by sterling qualities, can effect in the long run. Married at sixteen, and a widow at eighteen years of age, she experienced the necessity of providing for the requirements of every-day existence. An accomplished musician, and gifted with a voice of excellent quality, she played in operettas for some time until an affection of the larynx cut her theatrical career short. During a visit to Montpellier, yielding probably to the influence of environment in a town where two out of every twenty people are doctors, she studied for and obtained the diploma of midwife. A year or two later her taste for this new occupation stimulated her into working for the diploma of *officier de santé*, and later on, undeterred by the six years' curriculum and the preliminary degrees in arts and sciences, she resolutely carried the doctorate by assault. Then she came to Paris, and one fine morning was appointed *médecin de l'opéra*, a much envied, if not very remunerative position. Our neighbors have evidently surmounted those prejudices which still limit the ambition of women practitioners in this country.—*Medical Press and Circular*, August 15, 1888.

New Preserving Fluid.

At the meeting of the New York Pathological Society, June 13, 1888, Dr. T. M. Prudden presented the formula for a new preserving fluid, which had been referred to by Dr. Northrup.

Water	35 fl. oz.
Common salt	3 oz.
Saltpetre	6½ drachms
Carbolic acid	1¼ fl. "
Glycerine	4 fl. "
Amylic alcohol	1¾ fl. oz.
(or Ethylic alcohol	3½ fl. oz.

Specimens should be first soaked in a strong brine and then placed in a large quantity of this fluid. He believed the mixture would be found to serve a useful purpose in the temporary preservation of gross pathological specimens without changing their color or otherwise altering their general appearance. The mucous membranes were particularly well preserved in the fluid.—*Medical Record*, August 4, 1888.

NEWS.

—The number of cases of yellow fever at Jacksonville is decreasing.

—The Medical Society of Virginia will meet in Norfolk, October 23.

—The number of registered physicians in New York City is said to be 2350.

—Sir William MacCormac did a suprapubic lithotomy at the University Hospital, Sept. 26.

—The first Congress of Italian physicians will be held in Rome from October 15 to 18, 1888.

—The 75th annual meeting of the Vermont State Medical Society was held at Montpelier, October 11 and 12.

—Professor Bardenhauer, of Jena, is to be offered the Professorship of Physiology in the University of Greifswald, made vacant by Professor Budge's death.

—Dr. H. Frémy has been instructed by the French Government to visit the United States to study the methods of treatment of tuberculosis in hospital and in private practice.

—The corner-stone of a hospital, to be an annex to the present city hospital in Baltimore, under the control of the Sisters of Mercy, was laid September 30 by Cardinal Gibbons.

—Dr. Louis Bauer, of St. Louis, is said by the *International Medical and Surgical Synopsis*, September, 1888, to be convalescing from a remarkable combination of disorders, apparently the result of wound-infection.

—Succinamide of mercury is the latest claimant for favor in the hypodermic administration of mercury. It occurs in the form of a white, silky powder, very soluble in water. The watery solution is said to remain clear a long time, and to possess the additional advantage of not precipitating albumin held in solution in liquids; it gives no precipitate with serum from the pleura, and none with hydrocele fluid.

—The *Lancet*, Sept. 29, 1888, says that the Minister of Education has made the following appointments in the University of Vienna, ignoring the selections of the professorial Senate, which he considers were dictated by motives of personal liking rather than of public utility: Professor Emil Zuckerkandl, of Graz, to the chair of Anatomy; Professor V. Ritter von Ebner, of Graz, to the chair of Histology; and Professor

Theodor Puschmann, of Vienna, to the chair of the History of Medicine.

—On September 25, a Memphis physician was summoned to a patient who had just returned from Decatur, where yellow fever existed. He had many of the symptoms of that disease. It was subsequently determined, however, that the patient with the suspicious symptoms was intoxicated, and that the symptoms were due to an accompanying "bilious" attack. In the meantime the populace had become frantic with fear; and when they learned that there was no cause for alarm, they gave vent to many expressions by no means complimentary to the attending physician. These the *Memphis Medical Monthly*, October, 1888, publishes under some introductory remarks upon "man's inhumanity to man."

HUMOR.

CITIZEN. "Hello, Doc., have you seen Mike?" Doctor. "What Mike?" Citizen. "Microbe. He's looking for you."—*Memphis Medical Monthly.*

COMPARATIVE APPETITES.—Very stout old lady (watching the lions fed): "'Pears to me, Mister, that ain't a very big piece o' meat fer seech an animal." Attendant (with the greatest and most stupendous show of politeness on earth): "I s'pose it does seem like a small piece of meat to you, ma'am, but it's enough for the lion."—*Life.*

OVERTAXING HIS BRAIN.—Old Mrs. Bently—"Did you hear, Josiah, that the young student who has been boardin' at the Hendrickses is very sick?" Old Mr. Bently—"Yes, I heerd so; what's the trouble with him?" Old Mrs. Bently—"Studyin' too hard, I s'pose. The doctor says he's got information of the brain."—*The Epoch.*

PREPARED FOR THE ORDEAL.—Boggs: "Hello, Jagley! What on earth are you doing with that box under your arm?" Jagley: "Sh! It's a phonograph. I'm going to call on a young lady from Boston this evening, and this thing, with the help of a dictionary, will enable me to study out what she says at my leisure, after I get home."—*Judge.*

THAT ALTERED THE CASE.—Dr. Pillsbury (to patient): "My dear sir, all you need is plenty of outdoor exercise. Now, here is a little work that I would strongly advise you to read. It will teach you how to gain and preserve health. Its title is 'Physical Culture for the Million,' and—" Patient: "But, doctor—" Dr. Pillsbury: "Well?" Patient: "I wrote that book."—*Time.*

A DISCONSOLATE WIFE.—"I don't believe in these secret societies," said one Austin lady to another. "That's very singular," replied the other; "your husband is a Forester, a Knight of Pythias and a Knight of Honor, and you will have at least $10,000 when he dies." "But what good does all that do me," was the tearful response, "when he never dies?" and the poor creature burst into tears.—*Texas Siftings.*

SCIENCE AND FLEAS.—In answer to a correspondent who desired to know how to drive fleas out of a room, the Philadelphia *Press* says: Science has recently discovered that the muscles, or springs in a flea's legs, enable it to jump a distance equal to 200 times its length. If, therefore, you will place the fleas in a straight line, at a distance equal to 200 times their length, from an open door, and can train them to make the jump all together in the right direction, you may perhaps be able to secure their absence. Failing in this, consult a druggist.

OBITUARY.

CLARENCE G. HOLLISTER, M.D.

Dr. Clarence G. Hollister, who has on several occasions made valuable contributions to the columns of the MEDICAL AND SURGICAL REPORTER, died September 27, 1888, at his residence in Meadville, Pa., after a five weeks' illness with pneumonia.

Dr. Hollister was born at Garrettsville, O., about thirty-four years ago. He was educated at Wooster Medical University at Cleveland, and after graduating from that institution practiced his profession for a time at Sharpsville, Mercer County, Pa. He afterward removed to Cambridgeboro, and settled down to hard work in that place. He was young and energetic, and his capacity for work seemed to have no limit. Unfortunately his strength was overestimated, and his health was undermined by the severe and constant strain. In December, 1882, Dr. Hollister married Frances, widow of the late W. R. Gill.

About one year ago Dr. Hollister located in Meadville, and he was fast building up a lucrative practice when he was stricken with the fatal illness and was compelled to relinquish all work. He was a pure and upright man in every sense of the term, and all who had the pleasure of his acquaintance will regret to learn that he is no more.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

PROF. ALFRED STILLÉ, PROF. WM. GOODELL, PROF. D. HAYES AGNEW, PROF. H. C. WOOD, PROF. R. A. F. PENROSE, PROF. WM. PEPPER, University of Pennsylvania, PROF. J. M. DACOSTA, PROF. ROBERTS BARTHOLOW, Jefferson Medical College, PROF. CHAS. K. MILLS, Philadelphia Polyclinic.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

W. H. WALMSLEY & CO.

SUCCESSORS TO R. & J. BECK,

Manufacturing Opticians,

No. 1016 Chestnut Street, Philadelphia, Pa.

Microscopes,

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

THE

Zentmayer Binocular Microscope

IS NOT SOLD YET.

2 EYE-PIECES. 2 OBJECTIVES. (8-10 and 1-5.)
THE REGULAR "HISTOLOGICAL" STAND.

In good order. Can be used as a Monocular or Binocular—either. **$50 will buy it.**

Will be sent by express without extra charge.

Clinical Lecture.

RECURRENT PELVIC PERITONITIS.[1]

BY B. F. BAER, M.D.,
PROFESSOR OF GYNECOLOGY IN THE PHILADELPHIA POLYCLINIC.

Gentlemen: This patient is thirty-two years of age, and has been a widow two years. She has never been pregnant. The duration of the present illness is uncertain. Ever since puberty she has suffered more or less from the symptoms of which she now complains. She presented herself ten days ago, and stated that she was scarcely able to be out of bed, but being unable to employ a physician she felt compelled to go to a dispensary.

Her chief symptoms were sharp pains beginning in the left iliac region, deep-seated, and shooting across to the opposite side. She said the pain began with the onset of the last menstrual period, and that the flow was much more profuse than usual. Her menses usually last four days; at the last period the flow continued seven days, and was profuse, as stated. On questioning her it was learned that she had had numerous attacks of a similar character since puberty, especially in connection with the menstrual periods, and that of late years these attacks had been increasing in severity, the last one being the most severe she had had. The pain is at times almost unendurable. She becomes pale, and often during the attacks she suffers from nausea, and sometimes from vomiting. There is also some distension of the abdomen, with tenderness on pressure. The pain is less severe if she occupies the dorsal position, and she finds that bending the thighs upon the abdomen affords relief.

The question of differential diagnosis is an interesting one in a case of this character. You will note that the pain here is continuous and not intermittent in character, and that position and pressure increase rather than relieve it. If you will recall a case which we had in the clinic a week ago, you will remember that the symptoms somewhat resembled these, in the time of their occurrence—at the menstrual period—and in the sharp character of the pain. But in the former case there would be an attack of severe cramp-like pain in the centre of the hypogastrium or a little to the side, which would continue for a variable time, to be followed by a discharge of fluid or clotted blood, when there would be an interval of relief, to be followed by another attack. The pain was relieved by pressure; the patient stated that pressure gave her more relief than anything else, and that when the menses ceased she was apparently well. In the present case it is different. After the cessation of the flow the patient is unable to be about for days, and does not recover from the soreness and tenderness, but is more or less ill during the entire interval between the periods. In the first case we found stenosis of the cervical canal, and determined that the symptoms were due to obstruction in that canal so that the menstrual fluid could not readily flow out. We diagnosticated in that case congestive dysmenorrhea the result of stenosis. In the present case we found a different physical condition. The symptoms here are inflammatory in character and point to a local

[1] Delivered at the Hospital of the Philadelphia Polyclinic and College for Graduates in Medicine.

peritonitis, more especially of the left side, possibly, but not necessarily, involving the left ovary and tube. The pain of pelvic peritonitis is sharp in character and radiates from the affected side to the opposite, and often down the anterior portion of the limb, especially when the ovary and tube are involved. The symptoms here also resemble somewhat those of so-called ovarian neuralgia, except that in the latter case pressure relieves instead of increasing the pain; and the disorder is not attended by increase in temperature, and is not followed by exudation, although it usually produces nausea and vomiting.

This patient states that she began to suffer at the time of the occurrence of puberty; and on questioning more closely, we find that the symptoms at first resembled more nearly those of dysmenorrhea, the result of stenosis, due to an imperfection in development. They have since, however, gradually changed to their present character, which I ascribe to pelvic peritonitis; and as the trouble recurs with the menstrual period or from other cause, the disease has been properly termed "recurrent pelvic peritonitis." It recurs for the reason that the original cause and its consequences are still active.

It is probable in a case of this character that there is more or less inflammatory action with every period of ovulation, which is relieved or modified by the occurrence of the menstrual flow, which depletes the congested vessels and ends the process for the time. At the following period there may be an attack just as severe, and each succeeding attack may be more severe than the previous one, until the patient becomes so ill that she is compelled to call her physician; when, if an examination is made, it may be discovered that the uterus is only moderately fixed from a slight film of exudation on the peritoneal surface, or the exudation may be so great as to present a hard, board-like sense to the touch; or indeed the peritoneal pouch may be distended by an exudation so large in quantity as to present a well-marked tumor, such as we find in this case. The tumor formed in these cases is without shape, or rather it is not circumscribed by a smooth wall as in fibroid or ovarian tumor, but rather takes the shape of Douglas's pouch or the post-broad-ligament space. It is usually a little thicker below than above, but the general shape is flat. Both the ovary and the tube of the affected side may be involved in the inflammatory condition and surrounded by the exudation. In that case the tumor would be of somewhat different character. It would be larger, and probably circumscribed, but still irregular and fixed.

It has been said that this disease always begins as a vaginitis or endometritis, and extends to the Fallopian tube, finally involving the ovary and peritoneum. When abscess of the tube or ovary is found to exist in connection with the peritonitis, the origin is usually ascribed to gonorrhœal infection; when not attended with the formation of pus it is still said to be due generally to some septic material, non-specific or otherwise, admitted through the same channel.

There can be no question that this is true in many instances, probably in the majority of cases; but I believe it is also true that the disease often arises from traumatism, the result of congestion from interference with the menstrual flow, such as occurs from obstruction in the cervical canal, from stenosis or flexion of the uterus. The injury may also arise from coition, or from an external blow; or from cold, resulting in suppression of the menses. Obstruction in the cervical canal may result in regurgitation of menstrual blood through the Fallopian tubes into the peritoneal cavity. The obstruction may also be in the tube itself as the result of malformation of that organ; or the narrowing may be from inflammatory or other cause. Again, there may be such malformation of the fimbriated extremity of the tube as to prevent its grasping the ovary at the time of the rupture of the Graafian follicle. In the latter case the contents of the follicle would be discharged into the peritoneal cavity, and might result in the development of peritonitis. Early rupture of an extra-uterine gestation sac is another traumatic cause.

We must explain the development of the peritonitis in some cases from causes other than specific or infectious. This patient, for instance, first complained when she began to have her menses, and I do not think it would be scientific to jump to the conclusion in cases such as this that the disease was of gonorrhœal origin. It is not likely that at the early age of puberty a specific cause existed, and it would be unjust to the patient to ascribe it to that origin. It is more likely that the origin of the disease in this case has been in one of those developmental or traumatic causes enumerated above.

But whatever the cause, when called to a case of this character, you should at once make a physical examination, for the purpose of determining the locality and extent

of the disease, so that a proper treatment may be adopted. The patient should be at once placed in bed, for rest is one of the prime factors in the management of the case. If great pain and tenderness exist, a hypodermic injection of morphia should be administered. This will relieve the pain and facilitate the examination. If the necessary manipulation cannot be made without it, ether should be administered. The question to be settled first is the diagnosis, and I wish here to impress upon you the necessity of gentle manipulative measures, for I do not think there is a doubt but that many cases have been injured and made worse by a rough and awkward examination. First administer an antiseptic vaginal douche for the protection of both the patient and yourself, and see to it that your hands and instruments are rendered aseptic by thorough washing and emersion in an antiseptic lotion before they are used.

This patient was examined at her first visit ten days ago, and I found the uterus moderately fixed. On the left side and in the post-broad ligament-space there was a semi-solid mass of lymph extending into Douglas's pouch, flattened in shape and quite tender on pressure. It was not nodular, and seemed to become thin toward the upper portion, and to be of the general shape which you might imagine would be given to liquid glue or plaster of Paris which had been poured into a mould shaped somewhat as the post-uterine space is. I made a diagnosis of recurrent pelvic peritonitis, and ordered the patient to bed. I also ordered certain medicines, the first and most important of which was a saline laxative. For the relief of pain she was given a vaginal suppository as follows:

℞ Morphinæ sulph. . . . . gr. iii
Ext. Belladonnæ . . . . gr. iii
Ol. Theobromæ q. s.
M. et ft. supposit. No. vi.

Sig. One, morning and night for pain, if necessary.

She was also ordered the following mixture, to be used as a local application over the painful region.

℞ Tr. Aconiti rad.,
Tr. Opii . . . . . āā f℥i
Tr. Iodi . . . . . f℥vi

M. Sig. POISON. For *external* use only. Apply with brush to painful surface as directed, twice a day.

She was requested to paint the affected area with this mixture very thoroughly twice a day. The next most valuable remedy in a case of this character is the hot water vaginal douche, but it was omitted here because of the fear that it would not be administered properly, and might consequently result in more harm than good.

The patient was seen several times in the interval. She reports to-day that she is better, and that the pain has almost entirely disappeared. This will enable us to make a more thorough examination, and if possible, determine the cause of these recurrent attacks. The patient is placed in the dorsal position, and with the left index finger well warmed and lubricated I will proceed to make the examination, and describe to you the condition which I now find. In the first place, I am glad to be able to state that the semi-solid exudation tumor in the post-broad ligament-space, which was found at the first examination ten days ago, has almost disappeared; but in its place there is a hardened, irregular mass, which renders the tissues in this region fixed and rigid. I now place the fingers of the right hand on the hypogastrium, and by the conjoined manipulation which is permitted to-day, because of the absence of great tenderness, I am enabled to explore the post-uterine space more thoroughly. I discover in Douglas's *cul-de-sac* an indurated mass, irregular in shape, which is simply an extension of that which exists in the post-broad ligament-space. I am unable to outline the ovary or Fallopian tube, or any circumscribed or cystic condition resembling disease of those organs. I infer, therefore, that they are probably not involved in the inflammatory process.

I find on examination of the cervix uteri that that organ is somewhat enlarged, and that the os is very small—so small, indeed, that I can scarcely detect it with my finger. The body of the womb is also enlarged and firm, but it is mobile, only the cervix being fixed by the indurated exudate described a moment ago.

The absence of the semi-solid tumor which I discovered at her first visit, does not prove that I was wrong in my diagnosis, but simply that the serous portion of the mass has been absorbed, leaving the indurated irregular condition of the exudated material, which we find to-day. That is the history in these cases. Nature attempts, as soon as the inflammatory process has reached its height, to restore the parts to their normal condition by resolution of the exudate; but nature only partially succeeds, for another attack usually supervenes and arrests the process. Another attack supervenes for the reason that the original cause still exists, and also because the remains of the previous attack serve as an abiding stimulus to a

recurrence. The original cause of the disease in this case I believe to have been contraction or stenosis of the cervical canal, as described.

What will be the proper course of treatment in the present case under the existing circumstances? Will it be proper for me to begin at once a treatment for the purpose of rendering the cervical canal patulous, so that the menstrual fluid may escape naturally? If that means dilatation, I say emphatically No, for the manipulative measures which are necessary for the performance of the operation of dilatation would very probably cause a renewal of the disease.

As a rule patients who suffer from chronic pelvic peritonitis, which this practically is, are more or less broken in general health. They are more or less the subjects of nervous exhaustion, indigestion, anemia, and loss of flesh, as a result of the long suffering endured during the course of the disease. I believe that here the most efficacious plan of treatment is that which embraces REST as its guiding principle. It is unquestionably true that when the patient is allowed to exercise and follow her usual vocation, the attrition of the inflamed surfaces upon each other will tend to keep up the inflammatory condition. It is best, whenever it is possible, to remove the patient from the cares of her home, so that she may have mental as well as physical rest, free from domestic cares and especially from the marital relation. A general regimen, similar to that which was introduced by Dr. S. Weir Mitchell for the treatment of nervous exhaustion, and which consists of seclusion, rest, and diet, together with massage and general electricity, is the one which is most beneficial in these cases, whilst the local treatment which is necessary is being carried out.

Strict attention should at once be paid to the condition of the bowels, for constipation is one of the most troublesome accompaniments of pelvic peritonitis. I believe it often stands in a causative relation, and nearly always as a complication of the disease; first attention should be paid to the relief of this condition. Strict attention should be paid to the diet, and the food should be of the most nutritious character.

The local treatment should embrace those remedies which are thought to possess the power of stimulating the absorption of plastic material, either by a counter-irritant or stimulating action. The persistent and free use of the tincture of iodine, both to the hypogastrium and the fundus of the vagina, is of great value. But iodine alone is sometimes found to be so irritating to the skin as to make it necessary to discontinue its use; for that reason I am in the habit of prescribing the formula as given above, consisting of the tinctures of aconite and opium in addition to the iodine. This may also be applied to the fundus of the vagina instead of the iodine alone, either with a camel's hair brush or with the cotton-wrapped applicator. The vaginal application of the iodine should be made not oftener than every three days, and sometimes a longer interval is advisable, especially if the remedy is used in a concentrated form. If it is found that too much irritation has been produced its use must be discontinued for a time, and then remedies of a milder form may be substituted, such as the boroglyceride, or iodoform and glycerine, one drachm to the ounce, or glycerine alone may be used.

The remedy which I consider next in value to iodine, if not indeed preferable to it, is the hot water douche. But this remedy is liable to be abused when placed in the hands of the patient herself. It is a remedy the use of which should not go out of the hands of the physician or his trained assistant, the nurse. When administered by the patient herself the water is either used at too low a temperature or in too small quantity, or both. Further, she becomes tired of the pumping and of the position which she must assume, and fails to keep it up during the length of time required for the injection of the quantity usually advised—a gallon or two. The constrained squatting position is in itself injurious. I believe that the long continued use of warm water is followed by relaxation of the pelvic organs, and this would constitute another objection to the indiscriminate recommendation of this measure; for when it is placed in the hands of the patient, she is likely to continue its use for too long a period and after the indications for its use have disappeared. The remedy must be used in accordance with fixed rules, and under certain restrictions, and these I would class as follows: First. The patient must be in the recumbent posture, and in the dorsal position. Second. She must not administer the douche herself. Third. The water must be at a certain *high* temperature, which is best determined by the sensations of the patient. It should be as hot as can easily be borne, and the temperature gradually increased during its administration, for the patient will be able to endure it at a higher temperature after the current has been flowing a few minutes than when it is first begun.

I believe the douche is better than pumping, by Davidson's syringe for instance, because the application is more likely to be thorough and the effect to be maintained longer. For, even when the injection is given by the physician or nurse, the hand is liable to become tired of the pumping and the application stopped, for a time at least. It is the continuous application of the remedy which is most beneficial. For use in my private hospital, I have had made a tri-pod, five feet in length, with a hook in the center on which a bucket is easily hung. The bucket holds two gallons of water, and near the bottom is placed a stop-cock, to which is attached a tube provided with a nozzle and a stop-cock at its distal end.

The patient is placed on a bed pan, which I have modified after that devised by Meriman. The nozzle is then introduced into the vagina, and the stop-cock at the bucket turned by the nurse, the water being at a temperature of at least 110° F. The patient can then regulate the flow herself. The water is allowed to enter the vagina, dilating it, and flowing off slowly, so that the tissues are in a continuous hot bath, which can be kept up as long as desired—from ten minutes to half an hour or longer—care being taken to see that the proper temperature of the water is maintained by the addition of a fresh supply from time to time. The important point is not so much the amount of water, as its temperature and constant contact. The application of this remedy should be made once or twice a day, depending on its effect upon the patient.

Recently I have been using "Gordon's Utero Vaginal Irrigator." This instrument does away with the necessity of the pan, which is a great improvement. The mechanism of the instrument is simply the placing of a bulb similar in shape to that portion of Davidson's syringe which is used for the pumping. This bulb is placed near the end of the vaginal nozzle; its position, therefore, is in the orifice of the vagina, filling that space so that the water cannot escape except through a return tube which passes through the bulb. To this return tube a piece of rubber tubing is attached of sufficient length to conduct the water into a receptacle on the floor. With this instrument the water can be used at a much higher temperature, because it does not come in contact with the surface at the orifice of the vagina, which surface is more sensitive to the heat than that within the canal. Then another great advantage is the getting rid of the necessity of the pan. With these precautions in its administration, hot water is one of the most valuable remedies which we possess in the treatment of pelvic inflammations, and great credit is due to Dr. Emmet for introducing it and his persistence in keeping the remedy before the profession.

After all tenderness has subsided, much may be accomplished by gentle massage of the adherent pelvic organs, but great care and gentleness are necessary in the manipulation for fear of producing such irritation that the inflammatory process may be renewed. Then it is very necessary that organic disease of the Fallopian tubes and ovaries should be excluded before massage is begun, for if pyosalpinx or abscess of the ovary should exist and be overlooked, rupture of an abscess might result from the manipulation.

Before massage is begun, the patient should be placed across the bed, the hips resting a little over its edge and the feet placed on the knees of the operator. This relaxes the abdominal muscles, and gives greater control of the patient, so that the necessary manipulation may be thoroughly carried out. One or two fingers of the left hand should now be introduced into the vagina, while the fingers of the right hand are placed upon the hypogastrium; then the contracted ligaments, thickened membranes, and fixed uterus, ovaries, and tubes should be gently manipulated, and moved from side to side, or upward and downward, care being taken that the force used is not sufficient to lacerate adhesions, or even to so stretch them as to cause undue irritation. The proper amount of force is probably best regulated by the sensibility of the patient, and if pain is produced by the manipulation it should not be persisted in. This massage may at first be employed at intervals of two or three days, but later it may be used almost daily for a time. By this method it will almost invariably be found that the adhesions become attenuated and in many cases finally absorbed. On the other hand, in long-standing chronic cases, the adhesions may be of such size and strength that months may be required to produce any marked effect; and in rare cases the adhesions may be of such character as to be permanently organized, and almost incurably to fix the organs. Here operative measures of a nature to be described in a future lecture may be necessary.

In these marked chronic cases I have found, in addition to the massage, that

stretching of the fundus of the vagina, by firmly packing it with antiseptic wool, sometimes repeated daily, or at intervals of two, three, or four days, is of great benefit in overcoming the condition. The small rubber colpeurynter, distended with hot water, is a very efficient means of accomplishing the stretching, and I have used it with great satisfaction in some cases.

It has been advised that continuous pressure and stretching of adhesions be made by means of a large pessary; but I would strongly urge against such practice, for I do not think that good ever comes from it, and it is certainly often attended with harm.

There is another means of stimulating absorption in these cases of pelvic exudation which is now attracting considerable attention. That is electricity, both by the galvanic and Faradic currents. I have been using Faradism during the last few years in many cases of this character with benefit, and during the last year I have been using galvanism. This I have found to be of value in stimulating the absorption of exudated material. I think that it will eventually take a prominent place, when properly understood and properly applied, in the treatment of these cases, as well as in the treatment of fibroid tumors. There is no doubt as to the power of the strong galvanic current, applied according to the advice of Apostoli, to modify the nutrition in fibroid tumors, and generally to ameliorate the symptoms. I have had some marked cases to support these views. The same will apply to cases of pelvic exudation, and, I believe, also to some cases of disease of the tubes and ovaries which have not advanced to the formation of pus. Where pyosalpinx and abscess of the ovary exist, the only remedy is the removal of the diseased appendages by laparotomy. But I wish here emphatically to state that I do not believe that pelvic peritonitis is always the result of endometritis or salpingitis, nor that removal of the appendages is always necessary to effect a cure. I learned early in my experience the great value of prolonged rest and thorough local and general treatment in these cases. Benefit always follows, and in many cases a cure. As much cannot be said for removal of the appendages. In many instances removal of the tubes and ovaries in these cases does not cure the patient. I have, at the present time, under my care, for the same symptoms of which they complained before the operation, two of my own cases and several that have been operated upon by others. If that is the experience of one individual, it is probably the experience of all, and will swell the number of uncured cases to many. Do not understand me to say that I am opposed to the removal of incurably diseased uterine appendages, which cause great suffering to the patient, after other proper means have been used to effect a cure; for I am an advocate of the operation in such cases, as you have seen. But I plead for conservatism and due deliberation, and the exhaustion of means which do not subject the patient to an operation which is attended with danger to her life, and by which she is unsexed, so far as fertility is concerned; for many cases will get well without an operation, if time is given and skilful treatment faithfully pursued.

COMMUNICATIONS.

SULPHONAL; THE NEW HYPNOTIC.

BY HENRY M. WETHERILL, JR., M.D.,
ASSISTANT PHYSICIAN PENNSYLVANIA HOSPITAL FOR THE INSANE.

In the treatment of mental and nervous disorders it is of great importance to possess for insomnia a remedy of which sleep is the predominant physiological action. The medical profession has been waiting anxiously for the ideal hypnotic, and it seems as though the new German drug sulphonal approaches, in its effects, nearer to the ideal than any other of the recently discovered substances with which the modern, and especially the German chemists have filled the market. The claim to superiority of this new substance is that it has little if any physiological effect upon the vast majority of insomnious persons, except the important one of increasing and prolonging the natural tendency to sleep. Its action is said to be not in the least narcotic, but purely hypnotic. It is claimed for it that the pulse, pupils, temperature, respiration, appetite and secretions are unaffected, after its continued daily use, for an indefinite period; and that, finally, it is promptly eliminated from the system, principally by the kidneys, without irritation or detriment to those organs. It is a crystalline, white substance, with a slight tendency to efflorescence when exposed to the atmosphere, and is readily pulverizable, emitting, only when strongly triturated, a slight odor of sulphur; it is almost wholly tasteless, producing no dryness in the throat, and no unpleasant after-taste. It somewhat resembles urethan in appearance, and is formed in the process of the oxidation of

acetone in the presence of sulphur, and hence the odor when it is warmed or rubbed. Sulphonal is singularly insoluble in the potable solvents, such as water, the dilute acids or dilute alkaline solutions, or very dilute alcoholic fluids. It is soluble in a mixture of two parts of alcohol (ethylic, 95%) and one part of ether; but this is not potable, and any dilution of this with water precipitates the sulphonal.

In the estimate of the therapeutic value and effects of a drug, surely water is the only fair solvent, and if it cannot be a solvent, then it should be at least the vehicle employed, if it is desirable to exhibit the drug in a liquid form.

Sulphonal may be administered in powder, or a dose of the finely powdered substance may be suspended in three or four fluid-drachms of cold water, by means of gum arabic and syrup. This mixture should be thoroughly shaken before it is used, and but one dose prepared at a time, as the sulphonal rapidly settles to the bottom of the container.

The name sulphonal is composed of syllables picked out of the word which expresses its chemical composition—diæthyl-sulphondimethylmethan. Its actual solubility is in the proportion of one part to about one hundred parts of cold, and one part to eighteen or twenty parts of boiling water (which, of course drops it as it cools). It is unaffected by acids, alkalies, or oxidizing agents—a very stable compound. The following is its symbol—$(CH_3)_2.C(C_2H_5.SO_2)_2$. This substance was discovered and named by Prof. Baumann, who with Prof. Kast of Freiburg, tested its physiological action first on dogs, afterward upon normal human beings, finally upon insomnious persons, insane and otherwise. Their clinical observations proved that in doses of from two to three grammes (30 to 45 grains), given to persons in health, it produced lassitude, hebetude, sleepiness: when given in the same doses to persons suffering from nervous and febrile insomnia it produced a sound and refreshing sleep of from five to six hours duration, within from one-half to two hours after its administration. Subsequently, Prof. Cramer and Dr. Rabbas obtained similar results in a series of clinical observations upon insane patients in the Marburger Irrenheilanstalt. In no instance was its effect unpleasant or dangerous and it did not produce any evil after effect upon the circulation, respiration, appetite, digestion, secretions or excretions. The pupils and vision remained unaffected.[1] "Although somewhat slower in taking effect than chloral hydrate, the action of Sulphonal is more prolonged. Doses of two to three grammes proved safer and more effective than proportionately larger doses of amylene hydrate. Another peculiar and valuable attribute in sulphonal is that the prolonged use does not weaken its physiological effect; nor does it produce the desire for a narcotic that makes the use of chloral (and some other drugs) so dangerous. Additional and general investigation which will follow its introduction, will, no doubt, verify the above outlined observations, and insure the popularity of this new hypnotic."

The papers of Prof. Kast and of Dr. Rabbas were published in 1888, in the *Berliner klin. Wochenschrift*, April 16 and 23. Rabbas (see REPORTER, June 23, p. 823) considers it more desirable than paraldehyde or amylene hydrate, and as compared with chloral hydrate, sulphonal is less prompt and less profound, but more lasting in hypnotic effect. There is an unusual unanimity of opinion among all the investigators as to the merit of the new drug, and further evidence of clinical and physiological work will be found, as follows:—that of Langgard and Rabow, in the *Therapeutische Monatshefte*, for May, 1888; of Salgo in the *Wiener med. Wochenschrift*, No. 20; of Rosin, in the *Berliner klin. Wochenschrift*, April 30; of Œstreicher, *Ibid.*; of Cramer, in *Münchener med. Wochenschrift*, June 12, 1888, page 395; of Schwalbe, in *Deutsche med. Wochenschrift*, June 21, 1888, page 499, and of Rosenbach, in *Berliner klin. Wochenschrift*, June 11, 1888, page 481. Œstreicher thinks it better to give the dose several hours before bed-time, as it is rather slower to act than some of the other medicines of this class; but he found it none the less reliable in his hands, especially among the insomnious insane. Cramer's cases were all of the latter class. In 407 trials on 92 insane subjects he had "positive success" in 92.6 per cent.—*i. e.*, from 5 to 9 hours of unbroken sleep, occurring in about a half-hour after its administration. He had not an instance of unpleasant effect, "though in one case one ounce in six days, and in two others forty-five grains daily, for two months, were given." The published investigations of Schwalbe are of especial value and reliability, as they seem to have been thoroughly exhaustive and very carefully tabulated. He selected 50 patients, ill of various physical and some of mental diseases and disorders, all insomnious, and obtained a "prompt

[1] Notes on New Remedies, for June, 1888.

and satisfactory" hypnotic effect in 66 per cent.; a "relatively poor" result in 24 per cent., and a "negative" result in but 10 per cent.; but what is of especial value from our point of view is the fact that of 24 cases of purely nervous insomnia, success was complete in 90.3 per cent.

To such cases it seems best adapted, for in instances in which the sleeplessness was the direct result of pain or of decided irritation, success attended his efforts in but 44.4 per cent. Schwalbe agrees with the original observer Kast, that sulphonal is purely hypnotic, not narcotic. It seems decidedly most valuable in perturbed nervous and unbalanced cerebral conditions; but in no sense does it overcome insomnia the result of considerable pain or topical irritation. It does not, for instance, either diminish or allay the nocturnal cough of phthisis or bronchitis. Contrary to the experience of Kast, Schwalbe found it did not relieve cardiac dyspnœa. In but 12 per cent. of all cases investigated were there any ill effects, and these were confined to slight headache, or to transient vertigo. Schwalbe's experience with it in children was most satisfactory, in the dose of four grains. In male adults he gave it in doses of from fifteen to thirty grains; in female adults in less doses, from twelve to thirty grains; but in many adults of both sexes, much larger doses, from thirty-five to fifty grains were well borne, but were seldom necessary.

In the Department for Females, of the Pennsylvania Hospital for the Insane, its assistant physicians have been observing carefully its action upon a group of 8 patients with mental disorder, all of whom had been very insomnious persons; *all* resisting the sedative and hypnotic powers of the bromides, paraldehyde, urethan, tinct. hyoscyamus and valerian. Four of them resisted chloral hydrate and opium, in usual doses: all of them were controllable (i. e. slept) by hyoscine hydrobromate. All of this group are examples of subacute or chronic mania, melancholia or dementia; and all were much accustomed to the use of sedatives and narcotics, and always have to have "night medicine." *But one moderate dose* of sulphonal, suspended in water by means of gum arabic and syrup, was given to each patient about an hour before bedtime, and in no instance was the dose repeated later in the night. The group slept under intelligent observation.

The effects were carefully noted, and reduced to a tabular statement. The medicine was administered 230 times to these 8 individuals, an equal number of times to each. In every case but one, the dose was fifteen grains. In that case (one of well-known resisting power) the dose was twenty grains. The results were as follow: An excellent effect, *i. e.*, from 5½ to 9 hours of continuous sleep, in 196 instances, or 86 per cent. A fairly good effect, *i. e.*, from 4 to 5 hours of continuous sleep, in 15 instances. An imperfect effect, *i. e.*, from 2 to 3½ hours of continuous sleep, in 9 instances, and no hypnotic effect in 10 instances.

It is gratifying to note the general improvement which attends the regular nightly sleep produced by such a singularly harmless drug as sulphonal appears to be. In no instance has its administration (for many continuous nights) been followed by unpleasant effects. The patient rises with the usual appetite, free from headache or vertigo. In no instance did it produce an appreciable effect upon the pulse, temperature, respiration, skin, kidneys, or pupils. The digestion of food was not impaired by its regular use. Its sole appreciable physiological action was *sleep*, usually very restful and prolonged.

Now, if it has been used with so much good effect in overcoming the insomnia of chronic hospital cases of insanity, which have been plied with various sedatives until their susceptibility to the power of drugs is much weakened, and their power of resistance strengthened, how much more sleep-producing effect would a less dose induce in the simply nervous and weary or overworked and irritable nervous system? Would it not be also very valuable in the insomnia of disease of which severe pain is not a factor? Sulphonal will not ease pain, nor will it induce sleep when pain is present as a continuous sensation; but it will allay nervous restlessness, vigilance and excitement.

In regard to dosage, male adults require, as a rule, considerably more than adult females. Our commencing dose with the latter was eight grains, which was soon increased to twelve grains; but these doses were generally found insufficient, and further experiment proved the average effective amount to be fifteen grains, though there need be no fear in increasing the dose, if required, to the amount of from thirty to thirty-five grains. These observations were conducted with care, and are being continued. The results obtained in three members of the group referred to were from observations made by Dr. Henry B. Nunemaker, the remainder by the writer.

AN UNPREMEDITATED CÆSAREAN SECTION.

BY WILLIAM VARIAN, M.D.,
TITUSVILLE, PA.

On July 17, 1888, I was visited in my office by a medical practitioner of extensive practice, over thirty years experience, and considerable local reputation as a surgeon, and one who had been surgeon of a regiment in active service throughout the war of the Rebellion. He stated that he had a patient with an ovarian tumor, who, he thought, demanded operative treatment; and that he had referred her to me, as he himself did not do abdominal surgery. The doctor said he was well assured of his diagnosis, and had had the patient more or less under medical supervision for some months, although he had just arrived at the conclusion that she was suffering from an ovarian tumor. As this was not the first case of abdominal tumor referred to me by this physician, and as I had found his diagnosis on former occasions correct, I had no reason to doubt his diagnostic skill.

I saw the patient on July 18, and obtained the following history. She had been ailing for eleven months, suffering principally from distress and pain in the right iliac region. During the earlier months she had been nursing an invalid mother, and thought that her distress was due to the lifting and fatigue incident to her occupation. She first became conscious of an enlargement on the right side of the abdomen in April. It steadily increased, and during the past few weeks had been growing rapidly. Menstruation was regular in period and in duration, although less abundant than it had been a year ago. This statement was confirmed by an aunt who was present and who did the family washing.

The patient had never suffered from nausea or any disturbance of the stomach. Functions of the bowels, kidneys, and bladder had always been normal. She had never been obliged to rise at night to empty her bladder, except once, a week before my visit, when she had been feasting on watermelon during the evening. No frequent micturition during the day at anytime during her ailment. Her appetite and digestion had always been good; she had lost flesh rapidly of late, especially in the face and shoulders, and had never felt any abnormal sensation in the abdomen—no starting or jumping; no movement nor any sensation other than the pain and distress low down in the right side of the pelvis and region of the right ovary. Her breasts had always been large, and had not increased in size so far as she was aware; nor was there any darkening of the nipple and areola.

This was the history as obtained from the patient and her family. The young woman was thirty-three years old, bright and intelligent, a member of the Baptist Church, and held in high esteem by prominent and wealthy members of that congregation. Her answers to my questions were prompt, clear, and free from any apparent reticence. Neither in countenance nor in manner was there anything which would lead to a suspicion that her frankness was assumed.

The physical examination was made with the patient clothed only in her night-dress. The abdomen was about the size of a woman in the eighth month of pregnancy. The enlargement was principally on the right side. Palpation and percussion gave all the signs of an encysted dropsy. No thickening and enlargement or solid portion could be detected. Auscultation gave absolutely negative results. On vaginal examination I found the os rather long and firm, and was unable to reach the junction of the body and neck so as to trace the continuity of the two. The pelvis was filled above the brim with a fluctuating mass, which by combined abdominal and vaginal examination gave all the signs of a pure cyst. I had some difficulty in passing the uterine sound. The sound passed only 3¼ inches, and, when moved, apparently carried the womb with it. My diagnosis was cystic tumor of the right ovary. Two subsequent examinations during the following week, which were confined to abdominal palpation and percussion, gave no reason to change the diagnosis; and further questioning did not elicit anything to raise a doubt.

On July 30, 1888, I operated, with the assistance of Drs Barr, Young, and Luke, of this city. On reaching the cyst and evacuating a large amount of fluid, I discovered that it contained a fœtus. I promptly enlarged the abdominal opening, incised the uterus, and delivered a living child, which was presenting by the breech, and was evidently an eight-months fœtus. I rapidly removed the placenta, dilated the os from within with the index finger, and closed the incision as quickly as possible with silk sutures closely approximated, avoiding the mucosa. After perfecting the toilet of the abdomen, I closed the abdominal wound with silver sutures, inserting a

glass drainage tube in the lower angle, and dressed the whole aseptically.

The next day some blood was withdrawn from the tube, and the abdomen thoroughly washed with warm sterilized water. The following day the drainage tube was withdrawn, as all oozing had ceased. Eight hours after the operation the temperature rose to 101° F., and the pulse stood at 110. The next day, at 8 A.M., the temperature was 99 3-10° F., and pulse 100. From this time on both pulse and temperature were normal. Convalescence was uninterrupted, and on the twenty-first day after the operation the patient rode out in a carriage.

The child throve at first. There was a total absence of milk secretion. The child was fed artificially, and on the fifth day very *injudiciously* and in exact opposition to orders. A severe diarrhœa was the result, to which the infant succumbed on the seventh day.

The intense mortification felt by me at my error in diagnosis is but little modified by a successful Cæsarean section. That I was deceived by a breech presentation, unusual development of the amniotic fluid, an anomalous condition of the os uteri, and wilful misrepresentations on the part of the patient is more apparent to me than it will be to my critics. It is no consolation to know that other and more experienced members of my profession have met with similar experiences. Yet I freely present my mistake to the profession, that others may learn that it is not impossible even for the experienced surgeon to be deceived.

I failed to recognize the uterus when it was first reached partly because of its pallor, of the smallness of the exploratory incision, because of my inability by digital examination, after the cyst was reached, to detect anything but fluid contents, and perhaps still more because only four weeks before this operation I had successfully removed an ovarian cyst which so closely simulated a pregnant uterus in appearance that nothing but an unnecessarily large incision enabled me to decide that my original diagnosis was correct. My experience in this case satisfies me that the Cæsarean section is no more to be dreaded than other laparotomies, if opportunity is afforded to elect the time of operation.

—Dr. Frank P. Fry, says the *St. Louis Med. and Surg. Journal*, October, 1888, will occupy the chair of Anatomy in the St. Louis Medical College, made vacant by the death of Dr. B. J. Primm.

TREATMENT OF DYSMENORRHŒA BY MENTAL SUGGESTION OR HYPNOTISM.

BY ARTHUR C. HUGENSCHMIDT, M.D.
(UNIV. OF PA.), PARIS, FRANCE.

The following cases pertaining to the subject of gynæcology have occurred in my practice during the past year, and have been treated successfully by this method.

Case I.—Young woman, 27 years old, menstruated for the first time at the age of 11 years; since then her menstrual periods have been very regular, but each one of them is accompanied by a great deal of pain. Five or six days before the appearance of the flow, she has the usual unpleasant feelings described by most patients; but two days before, the pains become terrible, unbearable, the patient being compelled to lie down. These pains are situated in both ovarian regions, are very severe, and shoot down from each side into the corresponding thigh; they are accompanied by severe vomiting and headache. These symptoms last until the appearance of the flow, when the patient looses a great deal of blood, and then the pains disappear. From the train of symptoms alone, some organic malformation of the uterus or displacement of the same could be suspected; still I made no examination as different treatments had been tried before without success. I proposed to try the influence of mental suggestion.

This being assented to, both by the patient and her parents, I began the extremely short treatment in December last. On my first attempt to hypnotize her, I obtained no result by making her look at a diamond ring; on the second day, however, using the same method I obtained a better result, a light sleep, which is all that is necessary for the purpose. While the young woman was in this condition, I contradicted every one of the symptoms, which had been described to me, saying, "that she would have no more pains, no more vomiting, no more headache before, during or after her menstrual periods, that she was now entirely cured; she was then restored to consciousness.

At her next menstrual period, which came on a few days later, she felt perfectly well, had no pain, no headache, and no vomiting. The cure has persisted up to the present day; she has had no more return of her troubles and remains perfectly regular. In this case, these severe symptoms had lasted continuously for sixteen years; and five minutes time has been sufficient to effect a cure.

Case II.—In May last, I was called to a young woman, 25 years old, who complained of a very severe pain in the right ovarian region; the parts were painful to pressure. She had been in that condition for two days, and could walk about the room only with great difficulty, as any movement of her right limb would increase the pain; the symptoms present indicated a probable congestion of the right ovary.

Hypnotism was proposed as treatment and accepted; in this case, sleep was obtained by asking the patient to fix her attention upon my index finger; it took me about four minutes to place her in the proper condition, which is, as stated before, a slight hypnotic sleep. When in this state, I told her that the pain in her right side had disappeared from this moment; that she would be able to move her limb and walk about the room without any aid. On awakening, the patient stood up, began to walk, moved her right limb freely, and said she did not feel the least pain. Since then, these pains, which before would come on occasionally, have not returned.

Case III.—A young woman, 28 years old, menstruated for the first time when 12 years old; the menstrual period is very irregular in time, but not painful. When 19 years old, without any known cause, her menses suddenly disappeared. This amenorrhœa lasted one full year; then her menstruation appeared again, irregularly as before, but is now accompanied at every menstrual period by severe pain and vomiting.

The symptoms were as follows: three to five days before the flow, a general sense of lassitude, swelling of the breasts, and the ordinary signs of approaching menses; the flow then makes its appearance, and only three to four hours afterward do these extreme pains come on. They are, as in the first case, a double ovarian pain, extremely severe, extending down both thighs; the severity of those pains produces a general coldness of the surface of the body. In addition there is severe vomiting, but no headaches; these extreme pains last from six to eight hours, during which time the patient remains in bed, the legs flexed on the abdomen, especially the left one. Poultices produce a certain amount of relief. I hypnotized this patient in less than two minutes, she being a perfect subject. It is needless to say that a third person must always be present during this treatment—one of the family, especially if a young woman is the patient. As in the preceding cases, I announced the disappearance of the ovarian pains and vomiting at the next menstrual period, as well as the complete cure of the patient. Three days later, the patient menstruated, but experienced no pain whatever, and no vomiting; she felt bright and happy during the whole menstrual period. It is only two weeks since her last illness, but I have no reason to suppose that this patient will be cured in a less degree than the two preceding ones. I must add that these three patients were all well educated and very intelligent; hence the suspicion of having had to deal with persons of a low intellectual power is out of the question.

The method of treatment by mental suggestion is a very easy one, and does not, as is erroneously supposed, require a supernatural power on the part of the physician; any practitioner, who will study the subject, can do as well as any man living who uses this process.

Society Reports.

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING, AT WASHINGTON, D. C., SEPTEMBER 18, 19, 20, 1888.

Tuesday, Sept. 18, Morning Session.

The Association was called to order at 10 A. M., by the President, Dr. D. Hayes Agnew, of Philadelphia.

The first business was the delivery of the President's address, which was published in the Reporter, September 22.

The next paper was

A Contribution to the Study of Excisions of the Larger Joints,

by John Ashhurst, Jr., M.D., Professor of Clinical Surgery in the University of Pennsylvania, Surgeon to the Pennsylvania Hospital and to the Children's Hospital, Philadelphia.

(ABSTRACT.)

The remarks which follow are based upon the records of 120 cases in my own practice in which excisions of the larger joints have been required, and will refer especially to the operative method, the after treatment, and the functional value and limitations of applicability of excision in the case of each articulation. The 120 cases embrace 4 of shoulder joint, 19 of elbow joint, 40 of hip

joint, 51 of knee joint, and 6 of ankle joint excision.

Shoulder Joint. My four cases of shoulder joint excision have all terminated successfully; they all occurred in adults, three times in young persons, and once in an old person. The only case of special interest was that of a young married woman, aged 30, admitted to the hospital in a very prostrate condition, with acute necrosis of the left humerus and consequent pyarthrosis of the corresponding shoulder joint. The upper half of the humerus was removed at the first operation, and 20 days afterward the entire remaining portion of the bone including the condyles, the only osseous tissue left being a thin shell of small extent which adhered to the periosteal sheath on the inner surface. The patient recovered rapidly and acquired a surprising amount of use of the affected limb, and the increasing firmness showed that at least partial reproduction of bone was occurring. With the elbow supported, the patient could use her wrist and hand with considerable freedom.

In excising the shoulder joint, or more strictly speaking, the head of the humerus—for the glenoid cavity rarely requires more than superficial scraping or gouging—I have employed the method by a single longitudinal incision. I have endeavored to avoid wounding the tendon of the long head of the biceps, but when the parts are matted together by long-standing inflammation, the tendon is difficult to recognize and is often not seen until it has been severed.

In the after treatment, I attach much importance to the use of the well-known cushion devised by Prof. Stromeyer. It keeps the elbow out from the trunk, thus insuring the close application of the sawn humeral shaft to the glenoid cavity, and enables the patient to sit up or lie down at pleasure, without disturbing the dressings.

The functional utility of the limb after excision of the shoulder joint is upon the whole, quite good. The operation although seldom called for in civil practice, should be adopted without hesitation in suitable cases, such as those of suppurative arthritis, caries and necrosis, in which the indication for the operation is found either in pain, or in exhaustion from profuse purulent discharge. For plastic or rheumatoid arthritis or for simple anchylosis, the operation is not to be recommended, for the mobility of the shoulder compensates measurably for the stiffness of the joint, and the gain which would be obtained by operation is not sufficient to justify the risk.

Elbow Joint. Of the 19 cases of excision of the elbow joint, six have terminated fatally: 2 adults died within five days from traumatic gangrene following injuries so severe that amputation would have been the better operation; one died of delirium tremens; two from tubercular meningitis; and one, an old man, from exhaustion in the course of the fifth week.

In excising the elbow joint, I employ a longitudinal incision on the inner side of the articulation, taking care not to wound the ulnar nerve and to retain the attachment of the biceps. As a rule all the articulating surfaces should be removed, and within reasonable limits, the more bone that is taken away, the better, since flail-like union is less to be dreaded than anchylosis.

For the after treatment, I employ a somewhat obtuse angled, internal splint (Physick's splint) well padded and protected by oiled-silk. As bony union is to be avoided, it is not necessary to use a splint to render the part immovable. As soon as the external wound has become solid, the splint should be abandoned and the arm kept in a sling.

The functional result of a successful excision of the elbow is more nearly perfect than that of excision of any other articulation. Cases which justify this operation, are those of destructive, or gelatinous, arthritis, caries, necrosis, compound dislocation or fracture not so severe as to require amputation, and even simple anchylosis.

Hip Joint. I have 40 times resorted to excision of the hip joint in 37 patients. Twice have I excised, at intervals, both hip joints in the same individual, and once have I had recourse to re-excision in a case in which recurrent caries and recontraction followed some months after the patient left the hospital. This case terminated fatally from suppurative osteo-myelitis and septic peritonitis, at the end of a fortnight. Both cases of double excision did well. Of the 40 operations, 28 were followed by recovery, 11 by death, and one of the patients is still under treatment. Of the 37 patients, 25 recovered and 11 died. Should the patient now under observation die, the rate of mortality will be, as regards operations, 30 per cent.; as regards individual patients, 32.4 per cent.—a much better showing than the results given by most statistical writers.

The incision employed begins with a straight cut in the direction of the fibres of the gluteal muscle, curves around and behind the trochanter, and terminates in a straight cut corresponding to the axis of the femur. While affording free exposure to

the joint, it necessitates but little transverse division of muscular fibres. The head of the bone may be made to protrude, and then removed with the chain saw, or, under other circumstances it may be divided *in situ* with a small saw. It is my custom to remove both trochanters, and to round off the sawn end of the femur. In the *after-treatment*, I keep the limb well adducted with simple weight extension, with lateral support by means of sand bags. As soon as the external wound has become solid, and the patient can control the motions of the limb, he may be allowed to get about on crutches.

The functional result of hip joint excision must be somewhat differently judged from that of excision in the case of other articulations. In most instances the operation is performed only when death seems threatened by profuse suppuration or its consequences, and if the patient is relieved of pain and restored to a fair state of health and comfort, the treatment is amply justified. At the Children's Hospital in Philadelphia, where 20 of the 40 operations were performed, the rule is: not to operate, except in otherwise hopeless cases; and hence our recoveries represent so many lives saved. But in many cases excision not only saves life, but also restores the patient to the active duties of existence. In thirteen of the twenty-eight cases the patient obtained a useful limb, and in two of these the utility is regarded as perfect. The condition which most often calls for this operation is "hip-disease." I consider the operation suitable in certain cases of gun-shot injury. For uncomplicated anchylosis, it is not to be recommended, simple osteotomy being here a safer and surer method. Where anchylosis co-exists with extensive caries or necrosis, excision may properly be resorted to. I am afraid that the "age limit" for hip joint excision must still be maintained; in the case of the knee, I have ventured to extend the benefits of this conservative procedure to adults and even to middle-aged persons, and with great success; but excision of the hip joint becomes an operation of great and rapidly increasing gravity when once puberty is passed. Thus, while I count twenty-five successes and only four deaths in persons under fifteen years of age, I have had only three recoveries and no less than seven deaths in those older. In adults, the operation should only be undertaken with a clear understanding of the very great risks by which, under these circumstances, it is attended.

Knee Joint. I have performed 51 excisions in 50 patients, once having employed re-excision for anchylosis with recurrent deformity, in a case in which I had excised the joint nine years before. Once I amputated the thigh, ten weeks after excision, on account of beginning failure of health, and a good recovery followed. Of the 51 cases, but 5 have ended fatally, a death-rate of less than ten per cent.

In excising the knee joint, I have uniformly adopted the single transverse incision and have invariably removed the patella. The bone sections are commonly made with a Butcher's or bow saw. I take special care to remove all of the diseased synovial membrane as well as all patches of carious bone. In treating the large bursa beneath the quadriceps muscle, I have endeavored to hasten the cure by making a long incision on the outer side of the limb and either dissecting the bursa out bodily, or else scraping away its lining membrane with a sharp curette. If foci of softened and carious bone are found beyond the points at which it is safe to use the saw, I remove them with the gouge, and if necessary cut a channel through the osseous wall in such a way that the part may heal firmly without leaving a sinus.

In the after treatment, I employ a bracketed wire splint which, while firmly fixing both thigh and leg, enables the limb to be dressed as often as is needful without causing the patient pain. I have left the limb on the splint as long as six or seven weeks. After bony union is well advanced and the external wound is almost healed, I substitute a simple posterior splint or gutter of paste board. I think it important to use means of mechanical support for at least six months, especially with children.

The utility of the limb after successful excision of the knee is very great. The limb is stiff and slightly shortened; the foot is sometimes a little inverted, but the limb is strong, painless, and enduring, and enables the patient to lead an active useful life. As a substitute for amputation, and it is as such that I employ it, the merits of knee joint excision can not be gainsaid.

The cases in which excision of the knee joint is indicated are chiefly those of arthritis, especially of the variety for which years ago I suggested the name gelatinous; of caries; of neglected epiphysitis, etc The operation may properly be performed in anchylosis with deformity, and also in certain instances of wound of the articulation where the extent of the injury

is limited. In most traumatic cases, however, I believe that when any operation is called for, amputation will be found preferable.

Ankle Joint. I have resorted to this operation six times. Although about as often, I have removed the astragalus without interference with the tibia and fibula. Two of the six cases proved fatal from phthisis, one four months and the other nine months after operation. My impression is that this operation in itself is attended with very little risk.

In excising the ankle joint, I make an external incision curving around behind and below the outer malleolus, and carried forward as far as can be done without endangering the extensor tendons, and prolonged upward as far as needful in the line of the fibula. A second smaller incision is made longitudinally over the lower end of the tibia. It is usually desirable to remove the whole astragalus. This is perhaps the most tedious and difficult of all excisions, and the operation may be facilitated by rendering the part bloodless by the use of the Esmarch apparatus. The ankle is the only joint, with the exception of the wrist, in the excision of which the use of this apparatus seems to me to be desirable.

Some years ago I devised a bracketed splint for the after treatment of ankle joint excisions. This answers a good purpose. If antiseptic dressings are used, however, the part usually requires so little disturbance, that a simple posterior gutter of paste board supplemented by a fracture box, will be sufficient. The foot should be kept at right angles with the leg.

The cases which seem to me to call for ankle joint excision are those of compound fracture and dislocation, less severe than to require amputation, and those of localized caries and arthritis in which there is no suspicion of general tuberculous infection.

The large majority of my excisions have been performed without any of the so-called "antiseptic precautions" and the wounds have been dressed with simple oiled lint or with lint saturated with dilute alcohol. For more than a year past, however, I have employed the antiseptic method in almost all my large operations, using also antiseptic dressings in their after treatment and I think with benefit; though I am obliged to say that as regards the ultimate welfare of the patients, I have not noticed any gain. My best series of consecutive successes has been obtained under old methods, and I have not obtained any diminution of mortality by the adoption of the new. At the same time I have seen no ill results which could be attributed to the use of antiseptic measures; their use shortens the period of convalescence; and they have the merit on account of the infrequent change of dressings needed, that they greatly lessen the surgeon's labor. I know of no cases which require more personal and unremitting attention than those of excision, and it is an unquestionable advantage to be obliged to dress a wound only once a week, or every other week, instead of daily or every other day.

What will be the future of the operation of articular excision? The brighter triumph of conservative surgery in the hands of Fergusson and his successors, will it keep its place? or as some of our more enthusiastic brothers prophesy, will improved methods of dealing with joint disease in its early stages, make excision a matter only of surgical history and of antiquarian investigation? It seems to me that as the introduction of excision did not enable surgeons to abandon amputation for articular lesions, so improve treatment as we may, and educate the public as we may as to the necessity of being treated early, there will always remain a class of cases in which only by sacrificing a part, can we hope to save the whole, and in which excisions of the larger joints will therefore still be resorted to by judicious and conservative practitioners.

In opening the discussion, Dr. Lewis A. Sayre, of New York, said: The paper of Dr. Ashhurst has so thoroughly covered the ground, that very little is left to discuss. In excision of the hip joint I have been in the habit of using the wire cuirass, for the reason that it permits the carrying of the patient into the open air—an object not readily attained when the patient is kept in bed with the ordinary apparatus.

In regard to the antiseptic treatment which I practice entirely, I think that I may claim that I have used it without knowing it, from the time that I commenced practice of surgery. I think that my success has been largely due to the practice of pouring into the wound Peruvian balsam, which from the creasote (*sic*) it contains is an excellent antiseptic. I have also always arranged for thorough drainage. When I practiced my first excision in 1854, the operation was universally condemed. Some seem to now be going to the other extreme and performing excision of the hip joint too early, before a thorough trial of local and general treatment has been employed.

Dr. R. A. Kinloch, of Charleston, said: There is now no disagreement as far as the general question of excision is concerned, but there are still some important questions to be considered: In the first place, the distinction of traumatic from pathological cases amenable to operative procedure, and in the next place as regards the joints which are apt to do best in connection with excision for traumatism and for pathological processes. A consideration of the age and surroundings of the patients is of importance. Probably the best results follow excision in connection with shoulder joint excision for traumatism. In connection with gelatinous inflammation of the elbow joint, I have had satisfactory results even where all the material could not be removed.

I feel sure that if a few of the principles of so-called antiseptic treatment, cleanliness, thorough drainage and absolute rest, are adopted, many of the details may be omitted.

Dr. T. F. Prewitt, St. Louis, insisted on the necessity of getting cases of excision in broken down children out of doors as soon as possible.

Dr. F. S. Dennis, New York, called attention to cases of excision of knee-joint for disease beginning in abscess in the condyle. In these cases the abscess cavity breaks down after recovery, leading to the production of deformity. In these case he takes away all of the abscess cavity, saws away a corresponding piece from the tibia and brings the oblique surfaces together.

He has been in the habit of employing antiseptic dressings, removing the drainage tube on the third day, allowing the first dressing to remain five or six weeks.

In excision for injury, only enough bone to allow of free drainage should be removed.

Sir William MacCormac, of London, had heard with some surprise that the tendency seemed to be postpone excision of hip-joint until all other measures had failed. This is not the practice in regard to any other joint. In England the disposition is to perform the operation at an earlier period. Another point that he had not heard mentioned in the paper was in reference to the performance of operation in cases of old dislocation of the joint. He had performed this operation with success in old hip joint dislocation, and reported the case of a sailor coming under observation three years after the occurrence of dislocation of hip joint which had not been reduced. After the operation he could use the limb perfectly. He had been much interested in the recommendation of Dr. Ashhurst that a long incision be made to reach the subcrural bursa, a suggestion which he had not heard mentioned by any other surgeon.

Dr. E. M. Moore, of Rochester, had been somewhat surprised to hear a certain amount of indifference expressed toward the use of antiseptic surgery. He had found in his practice the greatest improvement follow the use of antiseptic dressing in these cases of excision. He cited several cases showing the result obtained.

Dr. John E. Owens, of Chicago, agreed as to the value of the wire cuirass and referred to a modification of this apparatus consisting in the substitution of a frame of gas pipe conforming to the outline of the body. On this the body is supported by means of flannel stretched between the two sides of the frame. Extension may be applied if desired by the use of adhesive plaster, counter-extension being provided for by elevating the foot of the frame. After keeping the patient in bed for 30 days, he tries to get them into the open air. He had found great advantage in keeping up a certain amount of extension after the patient was allowed to get up. By removing pain this enables the patient to move the joint more freely and thus tends to favor greater mobility of the part. He thought that there was no comparison between the antiseptic methods and those formerly employed.

Dr. Fred. Lange, of New York, referred to a class of cases in which the disease of the hip began in the tissue outside of the joint, the articulation becoming involved at a later stage of the affection. In these cases he recommended early operation, with the hope that in this way necessity for opening the joint would be avoided.

AFTERNOON SESSION.

The Association was called to order at 2 P. M. by President Agnew. The first paper was entitled

The Relation of Micro-organisms to Injuries and Surgical Diseases,

by Dr. Nicholas Senn, of Milwaukee. The paper was so extensive that in the limited time alloted to its consideration, the author was able to refer to but a few of the points which it contained. At the present time no argument is required to show that many special conditions are due to the presence of bacteria. In regard to the so-called

hereditary transmission of disease, the author held that the specific microbes of the specific diseases are transmitted directly from parent to child. In evidence of this he referred to cases of so-called hereditary osteomylitis in newly-born infants. In other cases while this same origin may be inferred we have as yet no direct evidence that such is the case. In regard to the question whether or not pathogenic micro-organisms exist in the healthy body, while the results of some observers point in this direction, the results of others are opposed to the existence of pathogenic organisms in the healthy body. The conclusion was that under certain circumstance, pathogenic organisms might be present. There is proof of this in cases in which after accidental injury, there is localization of these pathogenic organisms. Acute suppurative infectious osteomyelitis following slight injury or exposure was cited as an illustration of this fact. This localization is favored by certain anatomical conditions. The antagonism among micro-organisms was being considered when the time of the author expired.

In opening the discussion, Dr. Roswell Park of Buffalo, said he had done some work in this direction. He had examined pus from fifty-two sources and presented a table showing the number of cases in which pyogenic bacteria were found.

He had also prepared culture media with various antiseptics in different proportions, including carbolic acid, iodoform, iodine naphthaline, hydro-naphthol, resorcin, trichlorphenol, creolin, sulpho-carbolate of soda, boric acid, perchloride of iron, antipyrine, antifebrine and quinine. Almost the only one of these antiseptic jellies as thus prepared which has prevented all growths was hydro-naphthol, 1–100. This shows that hydro-naphthol can be relied upon as an antiseptic. Many of the bacteria grow freely on idoform jelly 1–100. Those which grew abundantly on iodoform jelly grow slightly on oxide of zinc jelly 1–100. Oxide of zinc was considered a better solid antiseptic than iodoform. The author thought that our present knowledge permitted us to associate certain bacterial forms with definite pathological lesions. In conclusion he presented the report of a case of abscess of the face in which he found the micrococcus tetragens. So far as he knew this micro-organism had never before been found in phlegmon in man.

Dr. Wm. H. Carmalt, New Haven, remarked that there was only one point to which he wished to refer; that was the alleged microbic origin of tumors. A great deal has been said in regard to the microbic origin of cancers and other tumors. He thought that the division of Virchow's class of granulomas into a class of tumors by themselves known as infectious tumors is correct. This class includes tubercle, syphiloma, lepra, lupus, actinomycosis and myelitis. These growths should be taken out of the class of tumors and assigned to a class by themselves. He had been unable to convince himself that tumors proper have a bacteriological origin.

Dr. N. Senn in concluding the discussion, said that the diseases enumerated in his paper included only those in which the specific cause had been isolated, cultivated outside of the human body, and in which the injection of this culture produced identical lesions. When these three things are done we have furnished positive proof that the disease is due to specific germs. Another class of diseases had been alluded to in the paper in which there was reason to believe from analogy that the affection was due to specific germs, although the three conditions above referred to had not as yet been fulfilled. So far no one had been able to show that the supposed bacillus of syphilis was the specific bacillus. That it is a specific disease cannot be doubted; that it is due to a microbe can not be doubted, but to establish this positively, experimenters must do what Koch did before he announced the specific origin of tuberculosis.

He was firmly convinced from his observations that tumors in the true sense of the word were not due to microbes. He had made tumor implantations for many years in animals and in justifiable cases in man both close to the original seat of disease and at remote points, without obtaining the least evidence of the *microbic origin* of disease.

Dr. W. W. Keen of Philadelphia then read a paper entitled

Three Successful Cases of Cerebral Surgery,

including 1. The removal of a large intracranial fibroma. 2. Exsection of damaged brain tissue. 3. Exsection of the Cerebral Centre for the left hand.

Case I.—Large tumor in the cerebrum probably arising from an injury at the age of three years. Tumor removed at 27. Hernia cerebri; recovery.

The patient, a young man of 27, at 3 years of age fell, striking his head on some bricks. At five he had measles, followed

by discharge from the right ear, impairing hearing. In February, 1885, epilepsy supervened, with intense pain in the head. About April, right-sided hemiplegia was complete, with aphasia. Right pupil was largely dilated and irresponsive to light. Vision imperfect.

When first examined by Dr. Keen, the only remnant of his former condition was epilepsy, hesitation of speech, and headache. In the attacks, the head and neck were turned to the left, while the body was twisted to the left. Convulsions general. Right pupil larger than left. A small scar was decided on as that resulting from the accident. This was half an inch above and in front of the left superior stephanion, 2¼ inches to the left of the middle line, and 3 inches behind the external angular process. The temperature on the left side of head was one degree (C.) higher than on the left. Dynamometer recorded, right 30°, left 35°. Left knee jerk normal, right subnormal. Diagnosis, probable tumor at the base of the frontal convolutions, involving the centres for the leg, arm, face, and speech.

The operation was performed December 15, 1887. An 1½-inch trephine was applied over the seat of the scar. This opening was enlarged to three inches. A tumor was discovered and removed. It weighed three ounces, forty-nine grains. Its size was 2⅞ inches by 2½ inches by 1¾ inches. Hemorrhage was abundant, and checked with difficulty. The wound was dressed antiseptically, drainage being provided for. The wound was followed by hernia cerebri. This showing no tendency to cicatrize, 34 skin grafts were applied. In ten weeks, cicatrization was complete. The elevation was then followed by a concavity. The tumor proved to be a fibroma—a rare form of intracranial tumor.

Case II.—Simple depressed fracture, followed in four months by epilepsy; thirteen months later trephinement and removal of damaged brain-tissue; recovery in seven days; cure of epilepsy to date.

Young man 25 years of age. In November, 1886, he fell 9 feet, receiving a severe blow on the right side of the head. Was unconscious for a considerable time. There was temporary loss of feeling in the three left ulnar fingers. On tapping the head on the right side he produced a "cracked pot" sound. Epilepsy began in March, 1887. Up to April, he had had 5 positive attacks. The diagnosis was traumatic epilepsy from depressed fracture. Centre for left hand and supra-marginal gyrus involved. Operation was done April 12, 1888. As soon as the flap was raised, the bone was found to be splintered. A 1½ inch disc of bone was removed. The dura mater had been ruptured. A small piece of bone had been forced through the dura mater and had become adherent to its under surface. The brain substance had also been ruptured. A cyst, quarter of an inch in diameter, was found connected with the piece of bone. All the brain substance that was altered in character was removed. This piece was ¼ inch long by ¾ inch in width. The button of bone was perforated and attached with chromic cat gut to the flap, so that the bone could not fall in upon the brain substance.

The wound was healed in seven days. After the operation, there was paralysis of the hand as regards flexion. That night flexion was recovered.

Note made May 28, 1888, shows that the disc of bone is adherent, mental and physical condition excellent, flexion of fingers normal. The iris of the right eye, 24 hours after the operation, responded separately as well as its fellow. This isolated symptom of want of proper reaction of the right iris, is probably a new observation, and may be valuable in the future in determining and better localizing the right centre. In this case there have been no epileptic attacks since operation. In the first case there were several attacks during the past summer.

Case III was one involving the removal the centre for the left hand and wrist. The operation was followed by recovery.

The patients were presented.

Wednesday, Sept. 19, Second Day.

MORNING SESSION.

Dr. Hunter McGuire, of Richmond, read a paper entitled

The Formation of an Artificial Urethra for Prostatic Obstruction.

It has been my lot to meet with a number of cases of hypertrophy of the prostate gland, which produce more or less obstruction to the passage of urine. These are conveniently divided into three classes.

1. Cases where the obstruction was due to temporary congestion of an already enlarged gland, which yielded to the ordinary treatment and did not return.

2. A class of cases where the obstruction to the passage of urine was permanent but

not great. Attention to the general health, the occasional introduction of the catheter and washing out the bladder were all that the cases required These cases are, however, never free from danger from exposure, etc., and gradual enlargement may go on and bring about the condition met with in the third class.

3. In these cases the obstruction is great and fixed, micturition is frequent and difficult, perhaps impossible without the aid of the catheter. The introduction of the instrument grows more and more difficult; offensive residual urine is always present and the general health suffers greatly. Cystitis, localized or general is a painful and pronounced symptom. Violent tenesmus of the bladder, provoked by the obstruction, injures the vesical ends of the ureters; possibly a reflux of stale urine is driven into these canals and ureteritis follows, then pyelitis and pyelonephrosis, from which the patient dies.

The paper was devoted to a consideration of surgical interference in this third class of cases. He was led to resort to the measures described from the following circumstances: —During the past eight months four cases of stone in the male required the supra-pubic operation. Two because of organic stricture; one because of the large size and hardness of the two calculi the bladder contained; the fourth because the stone was large and hard and the patient two anæmic to bear the shock and loss of blood which often accompanies section through the rectum.

In one of the cases of stricture in a man 65 years of age, the patient had two years before coming under obseration a second cause of obstruction. A well organized stricture was found in membranous portion of urethra. Prostate was enlarged, more marked on the left side. Urine showed no evidence of renal disease. An oxalate calculus ¾ in. in diameter was also recognized. The high operation for stone was performed. The bladder walls were found thick and unyielding, and contracted. The left side of the gland jutted into the bladder one and one half inches further than the right side. The middle lobe was of the size of the thumb and almost completely closed the urethra. It was decided to retain a fistulous opening through which urination could take place. This tract was 2½ in. long and extended upward and forward. In its passive state it was closed by the pressure of the parts through which it passed. When the bladder became full and contracted the urine was forced through the fistulous tract. He can now retain water for two or three hours, and has voluntary power both to retain and expel urine.

Case two was that of a man 69 years of age who had been cut for stone in 1881. In 1883, I found the prostate enlarged and cystitis present. He was given a gum catheter and shown how to use it. In 1886 electrolysis was employed without success in trying to reduce the size of the prostate. July 4, 1888, an operation similar to that performed in the first case was done with equally good results. At times he is able to retain urine for six hours. He never has any desire to empty the bladder no matter how full the organ is.

Mode of operation. The night before the operation the bowels are opened. On the day of operation 15 to 20 grains of quinine are administered. Antiseptic precautions are adopted throughout. The bladder is washed out with a weak solution of carbolic acid in hot water. An empty gum bag capable of holding 12 ounces is passed into the rectum. About twelve ounces of water are then introduced into it. This pushes the bladder above the pubes. The bladder is next filled with a hot solution of carbolic acid. The use of force should be avoided. The penis is tied with a piece of rubber tube to prevent escape of the fluid. A vertical incision is next made, beginning 3 or 4 inches above the pubes and extending to the symphisis. This extends to the linea alba. The incision in the latter structure should be from three-fourths to one inch shorter than that through the skin. When the transversalis fascia is reached, it should be divided, but not for more than two inches, but should reach to the pubic bone. The fat and cellular tissue between the transversalis fascia and bladder is separated with the handle of the knife. This tissue should be disturbed no more than necessary. The bladder is now drawn forward with a tenaculum and opened as low down as possible. The interior of the organ should be carefully explored with the finger.

Sutures should now be applied extending down to, but not including the recti muscles. The opening left in the skin should be at the upper extremity of the wound, so that the fistula will be oblique and from two and one-half to three and one-half inches in length. A catheter is passed through this opening. If the catheter causes annoyance it may be at once removed, otherwise it is better to allow it to remain a few hours. The dressing consists of a pledget of absorbent cotton changed

as often as necessary. In none of my operations have I met with the peritoneum.

In the after treatment it is important to keep the urine acid, for acid urine is aseptic. In operating on these cases and in the high operation for stone, the amount of blood lost has not exceeded two drachms.

Dr. John H. Packard, of Philadelphia, read a paper entitled

Supra Pubic Cystotomy.

The present paper was supplementary to one on the same subject read by Dr. Packard at the last meeting and was intended to correct an accidental omission of the views of Sir Henry Thompson. These were now considered, extensive quotations from the works of this author being given. Two cases were reported in one of which the operation was performed for the removal of a portion of silver catheter broken off in the bladder; and in the other for the removal of a piece of rubber catheter said to have been broken off several months previously. In this case a stone weighing 571 grains was removed, in the interior of which was found the foreign body.

Dr. S. W. Gross, of Philadelphia, in opening the discussion, thought that Dr. McGuire was to be congratulated on having introduced a new operation based upon the mechanism of the bladder and the physiology of micturition: the formation of a artificial urethra in a new position. The various operations which had been performed for the relieve of prostatic obstruction were next referred to, the operations of Harrison, Mercier, Bartinini and McGill were considered.

Dr. Wm. T. Briggs of Nashville, thought that perhaps in the cases reported by Dr. McGuire, a better result might have been obtained by lateral lithotomy, provided the stone were not too large to be removed by that route; for he had noted that after incision into the prostate the gland diminished in size and after the wound had healed a catheter could be passed in cases in which its use was before impossible. The perineal operation allows of freer drainage. Under some circumstances the supra-pubic operation is valuable one. This is especially the case where the stone is so large that its removal through the perineum is liable to produce serious injury of the soft parts. It is however often possible through an incision in the perineum to so break the stone as to permit its removal. Every case should be studied by itself, in some one operation is the best, in others, another is most suitable. All the circumstances of the case must be taken into consideration.

Mr. Reginald Harrison, of Liverpool, said that there are two general methods of relieving obstruction due to enlarged prostate, one by attacking the gland through the bladder and the other through the perineum. In his operation he makes a median or lateral incision through the perineum according to circumstances. The obstructing prostate is next divided with considerable freedom and a drainage tube of considerable size introduced. From this operation, he gets good results. Perineal lithotomy is preferable to the supra-pubic operation because the lateral incision gives sufficient room for all manipulations. It gives an ample opening for the removal of a stone of considerable dimensions. It also permits of the more or less permanent drainage which these cases require. He had also through a perineal opening used the perineal lithotrite with success. All methods of operation should be remembered and each employed in those cases where it seems indicated.

Professor Thomas Annandale of Edinburgh had come to the conclusion that if an operation is to be performed for the relief of prostatic obstruction, the perineal operation is the best. This allows of examination of the bladder, permits drainage and probably causes a diminution of the hypertrophy. It enables you to occasionally remove a portion of the enlarged prostate when this assumes a pedunculated form. The speaker exhibited a rubber tube which he had found useful in cases of Harrison's operation, when a permanent tube is required.

Dr. A. Vander Veer, of Albany, said that the testimony presented in his paper last year was in favor of the perineal opening so far as drainage was concerned. He had employed Harrison's operation in a number of cases and the results had been such as to impress him favorably.

Mr. Arthur Durham, of London, emphatically endorsed what had been said in regard to operation for stone, that no one operation is applicable to all cases. It is a great mistake to be men of one method, especially in surgery. When we hear a man say that he treats all his cases of fracture in such a way, all his cases of stone in such a way and all his cases of prostatic disease in such a way, we may be sure that such a man has a very small practice and experience, or else is a very great fool. In cases in which stone in the bladder is complicated with enlarged prostate, the perineal incision

seems to me to be better than the supra-pubic. He described a method of performing perineal lithotomy which is performed with satisfaction at Guy's Hospital. This consists in the use of a straight staff, the groove extending to within one-third of an inch of its extremity. A knife with a straight back is passed through the perineum until it reaches the groove, then carried along the groove to its extremity and, the point of the knife being held in close contact with the staff, the two are carried forward into the bladder, thus avoiding many of the risks of the operation as ordinarily performed. In concluding, he referred to the great improvement of the Bigelow operation over the old method of crushing for stone. He had no doubt that this method renders both lateral and supra-pubic lithotomy much more rare than they have been in the past.

Prof. Hingston, of Montreal, believed that the supra-pubic operation was one to be performed only in exceptional cases. These he classified as follows. 1. In those cases of stricture in which the obstruction can not be overcome in time to relieve the patient of great suffering. 2. In cases of prostatic obstruction. 3. In cases of tumors of the bladder which would interfere with the lateral operation. 4. In cases where the stone is too hard or too large to be removed either by lithotrity or by lateral lithotomy. He had himself removed without injury to the soft parts, a stone weighing five ounces and five drachms.

Sir Wm. MacCormac, of London, had performed the operation of supra-pubic cystotomy occasionally. He had never seen any untoward consequences and the operation seemed to be devoid of all risk. He did not consider that drainage was necessary after this operation. The bladder empties itself freely and the drainage tube is a source of irritation.

Dr. Hunter McGuire said that the only object of his paper was to describe the two cases in which he had made an artificial urethra to relieve prostatic obstruction. The various operations referred to were not applicable to all cases, while the formation of an artificial urethra could be done in all cases. He was surprised to hear that supra-pubic cystotomy was considered dangerous. It had the advantage of avoiding some of the unpleasant consequences of the lateral operation, such as dribbling of urine and impotence.

Dr. J. H. Packard did not want to be considered as an advocate of supra-pubic cystotomy. It had however been shown that the dangers attributed to this operation, did not exist. He considered that the operation was a valuable resource in certain cases. After this operation he had noted diminution in the size of the enlarged prostate. This he attributed to the rest afforded the bladder. It will take place in whatever way the rest may be obtained.

The President, Dr. D. Hayes Agnew, being called upon, said the ground had been so thoroughly covered that there was little to be added. He agreed with those who held that no single operation was applicable to all cases. The supra-pubic operation may be appropriate in certain cases, while in others the perineal operation is the proper one. In order to avoid the unpleasant consequence which occasionally follow the perineal operation in children where the prostate is small, I avoid the introduction of the finger into the bladder and remove the stone with forceps not much larger than the staff.

While there may be no danger in the supra-pubic operation in skilled hands, yet with the inexperienced operator there will be risk of opening the peritoneal cavity. He thought that a number of cases had been reported of rupture of the bladder following injection of the organ after dilatation of the rectum with the rubber bag.

A paper entitled

Forty Years of Chloroform and Ether in Louisville, Ky.,

by Dr. D. W. Yandell, of Louisville, was read by title.

The following are the officers of the Association for the following year: *President*, Dr. D. W. Cheever, of Boston; *Vice-Presidents*, Dr. T. W. Richardson of New Orleans and Dr. John B. Roberts, of Phila.; *Secretary*, Dr. J. R. Weist, Richmond, Ind.; *Treasurer*, Dr. P. S. Conner of Cincinnati; *Recorder*, Dr. J. Ewing Mears, Phila.; additional members of Council, Dr. W. F. Peck of Davenport and Dr. S. W. Gross of Phila.

The next meeting to be held, beginning the second Tuesday of May 1889, in Washington. Chairman of Committee of Arrangements, Dr. J. S. Billings. Member of Committee of Arrangements, Dr. J. Ford Thompson of Washington.

AFTERNOON SESSION.

Dr. W. T. Bull, New York, read a paper entitled

The Surgical Management of Typhlitis and Perityphlitis.

The author reported seventeen cases oper-

ated on by himself. These he divided into three groups. The first included ten cases in which abscess was opened by incision without opening the general peritoneal cavity, at periods varying from seven days up to six weeks from the beginning of the attack. All of these cases recovered; the second group included six cases in which laparotomy was performed seven times for supposed perforation (one patient being operated on twice). The earliest operation was at the expiration of 36 hours, the latest on the fifth day. Death occurred in two of these cases, one from incomplete operation and the other from imperfect technique; the third group contained but one case, but the author hoped that in the future more would be reported. In this case laparotomy was performed in the presence of threatening symptoms, on the twelfth day, of an attack of perityphilitis. No pus was found and no signs of recent peritonitis. The appendix was surrounded by old adhesions. The diagnosis of this class of affections was then referred to.

The operations described were laparotomy and simple incision of the abscess. Antiseptic precautions should be adopted in both. The incision for laparotomy should begin a finger's-breadth above the right Poupart's ligament and extend upward four inches. The peritoneum should be divided at the lower angle of the wound. Adhesions are then separated and any pus found, evacuated. The intestines should not be allowed to escape through the wound. The region behind the cæcum must be carefully examined. If there is perforation or gangrene of the appendix it should be removed at its junction with the cæcum. After thorough washing out of the cavity a drainage tube should be introduced, passing to the bottom of the iliac fossa.

For opening an abscess, the incision should start from the point before mentioned and continue either parallel with the ligament or more vertical, according to the position of the abscess. Incision may be required above and parallel with the crest of the ilium if the maximum of tumefaction is found there.

A brief report of the cases operated upon was then given, and the following conclusions presented:

Our present knowledge justifies the statement that both the cæcum and appendix may be the starting point of an inflammation spreading to the peritoneum or to the peritoneum and cellular tissue of the illiac fossa, constituting a complicated lesion which for convenience sake we may call "perityphilitis."

This may be, in its clinical course, resolving or suppurative, each marked by definite symptoms in some cases; in others difficult to recognize.

Needle-exploration is a justifiable and desirable method of diagnosis, though attended by some risks. These may be reduced to a minimum if care be taken to reserve the practice for cases where the symptoms have lasted several days, and where a distinct indication "tumor" can be made out.

Suppurative perityphilitis may be a spreading or limited (circumscribed) peritonitis. Both begin with the same set of symptoms, and it is important to discriminate between them in the first 24 or 48 hours or even on the third day.

The presence of any of the local or constitutional signs of general peritonitis justifies the diagnosis of a spreading or generalization, and calls for the performance of laparotomy and the repair of the lesions found.

The absence of these signs or their strict localization warrants delay of a varying length. Any time after a week the abscess may be opened by an incision which must reach the pus, whether it be extra- or intra-peritoneal.

In doubtful cases, the risk of the operation is less than the risk of the disease.

The propriety of exploring and removing the appendix in recurring cases must still remain *sub judice*.

Dr. J. Ewing Mears, of Philadelphia, read a paper entitled

The Propriety of Surgical Interference in Perforating Typhoid Ulcer.

The present state of our knowledge and our largely accumulated experience have enabled us to define, with a degree of exactness, the limits of surgical interference in certain affections of the abdominal organs. The researches of Senn have shown that complete extirpation of the pancreas is invariably followed by death, while partial excision is a feasable operation. We are also able to define the limits of operation in affections of the spleen and kidneys. We may venture to approach the discussion of operative interference in perforating typhoid ulcer with the feeling that here we may be compelled to define a limit to the employment of surgical measures, not without regret at our inability to overcome the

barriers which oppose success, but with a desire to maintain always the good repute of surgical science and art.

A clear distinction must be made between the widely different conditions which precede and follow perforation in typhoid ulcer and in ulcerations of the intestinal canal due to other causes. In typhoid fever, in addition to the intestinal lesions, there is a general degenerative process involving all the important organs. In traumatism, the general condition of the patient may be good. In inflammatory conditions, while the general system may be profoundly impressed, the lesion may be regarded as local in its nature. In diseases of a chronic character, the system has accommodated itself to the impression made by the morbid affection, and the degenerative changes which may occur are not usually general in character.

The symptoms are usually quite distinctive. Death, as a rule, occurs on the second or third day; rarely the fatal result may be postponed two or three weeks, and instances are recorded in which recovery has taken place, adhesions having occurred between the edges of the perforation and adjacent parts.

A careful search of current medical literature reveals but four cases of surgical interference in perforating typhoid ulcer, in all of which a fatal result occurred. The reports of these four cases were given in detail. These cases were operated on by the following surgeons: Prof. Kussmaul, of Strasbourg, Mr. T. H. Bartlett, of Birmingham, Dr. R. B. Bontecou, of Troy, N. Y., and Dr. T. G. Morton, of Philadelphia. In Prof. Kussmaul's case the disease was severe and perforation occurred early when the infectious process was at its greatest height and the vital forces at the lowest point. In Dr. Morton's case the disease was mild, "a walking case." In both of these cases the shock consequent upon the perforation was prompt and profound. In the first case operation was performed within a few hours, but death without reaction from shock occurred in eleven hours. In Dr. Morton's case operation was resorted to twenty hours after the accident. Six hours after operation, the patient sank into a collapsed condition and died. The operations in these cases were performed by surgeons of experience, under strict antiseptic precautions and within a reasonably short time after the accident. We must therefore look for the cause of failure in the systemic condition; the degenerated and devitalized condition of the organs and tissues caused by the infectious process in active progress, utterly deprived of the power to resist the shock of operation; or in the condition of these structures beginning to recover from the effect of the poison in milder form, extremely sensitive to any rude impressions and wanting in tone and power of resistance. It is in the latter conditions alone that the surgeon may hope to achieve success by surgical interference, and then only when such methods are adopted as will reduce to the lowest point the shock of operation.

The following propositions and suggestions were offered: 1. Surgical interference is not justifiable and should not be instituted in cases of typhoid fever in which perforation occurs when the infective process is at its height. 2. In mild cases of the disease in which the pyrexia has not been of high grade, and in which perforation occurs at the end of the third week, or later when the stage of convalescence is fully pronounced, laparotomy may be performed. Surgical interference in cases of this character is advocated with the hope that if the method of operation suggested by Lücke—laparotomy with the creation of an artificial anus—be adhered to, success may be attained. 3. Rapidity of operation will be an essential factor in the achievement of success—through which prolonged exposure of the cavity will be avoided and shock greatly lessened.

Dr. B. A Watson, of Jersey City, in opening the discussion, said that, in cases where perforation has occurred the sooner operation is performed the better. He considered that it is safer to make an exploratory incision than to use the needle. In regard to the paper of Dr. Mears, it covered the ground completely. In those severe cases of typhoid fever where perforation occurs and life is about ebbing away, it would be folly to resort to operation, but in mild cases where perforation occurs the operation should be done early.

Dr. R. B. Bontecou, of Troy, N. Y., had performed the operation in one case of perforation in the third week of typhoid fever; the patient, however, died. He thought that it would succeed in some cases, as in those in which perforation follows imprudence during convalescence.

Dr. O. B. Nancrede, of Philadelphia, thought that the proper place for incision was two inches to the right of the anterior superior iliac spine. He had operated in two cases; in the first there was no pus, but three or four perforations were found. This

patient recovered. The second case was that of a child operated on four days ago. The patient had done well since the operation.

Dr. Gordon, of Portland, referred to the absence of symptoms met with in these cases, and cited a case in which the symptoms were not distinct but in which a pint of pus was found, with general peritonitis and perforation of the appendix. In this case an incision on the right side would not have reached the pus.

Dr. D. W. Cheever, of Boston, reported a case in which strangulation of an old hernia occurred in the third week of typhoid fever, the patient not being seriously ill. A simple incision through the sac was made and the bowel replaced, but the patient did not rally from the shock.

Dr. W. H. Carmalt, of New Haven, referred to a case which had come under his observation with symptoms of internal obstruction. Operation was suggested but refused. The patient died and the autopsy showed perforation of the appendix, extravasation of fæcal matter. The appendix was attached deep down in the pelvis where there was a small collection of pus. This was reached only with the greatest difficulty and after turning the intestines out of the abdominal cavity. This abscess was unaccessible to any of the ordinary methods of operation. The careful exploration of the rectum in this case failed to reveal any sign of disease.

Dr. Joseph Ransohoff, of Cincinnati, thought that the general impression that perityphilitis is necessarily associated with perforation, was an error. There are two classes of cases. In one there is a distinct tumor and in these early operation is by no means indicated. In these cases adhesions have formed and there is a natural tendency to cure. In these cases the abscess finally perforates the abdominal wall or is relieved by incision. The second class is that in which the symptoms of perforation develope suddenly. In these cases the incision should be median.

Dr. T. F. Prewitt, of St. Louis, thought that there must be many cases of inflammation in the region of the cæcum that never suppurate. He recalled a number of these cases, only two of which had died, one from perforation and the other an old man from exhaustion incident to an intestinal affection. In almost all of these cases the patients had had three or four previous attacks.

Dr. Reginald H. Fitz, of Boston, held that the appendix was the seat of disease in the great majority of cases. The symptoms usually enabled the physician to make a correct diagnosis. The use of the exploring needle was not considered advisable. The cæcum can always be readily found by remembering that it is attached to the colon.

Dr. George W. Gay, of Boston, remarked that in the cases on which he had operated, recovery had followed in those cases in which offensive pus had been evacuated, while in those where he had found only serum and flakes of lymph, a fatal resulted followed operation.

Dr. John H. Packard, of Philadelphia, read a paper on

Simultaneous Ligation of the Right Carotid and Subclavian Arteries for Aneurism of the Innominate.

The symptoms of aneurism followed a blow upon the chest. The patient died three days after the operation with symptoms of suffocation. No autopsy could be obtained.

[to be continued.]

Hospital Notes.

Hospital of the University of Pennsylvania.

Reported by Henry W. Cattell, A.M., M.D., Assistant Demonstrator of Chemistry, University of Pennsylvania.

Amputation of Thigh for Giant-celled Sarcoma.

Prof. John Ashhurst, of the University of Pennsylvania, introduced Prof. von Esmarch as his clinic Sept. 22, 1888, as occupying the Chair of Surgery at the University of Kiel, and one of the most distinguished of German Surgeons.

The Professor is a venerable looking man and to him and Silvestri belong the honor of first using what is known as the Esmarch bandage or apparatus for bloodless operations. The professor speaks English with a perfect accent but is at loss now and then for a word. He began by saying:

"While I am relating the history of the patient I always prepare my hands by washing them antiseptically; this saves the time of cleansing them beforehand and then as the hands are washed at the last moment one is sure that they are thoroughly aseptic. The patient that is to be operated on to-day is a woman suffering with a large growth involving the left knee. This growth has

grown within the last eight months and is no doubt a giant-celled sarcoma and will require an amputation of the thigh. I prefer to perform the circular amputation by a single incision. I will now apply the bandage and tourniquet, but will only apply the bandage up to the knee, or otherwise, by the pressure some of the giant cells might be driven into the circulation and the disease be propagated in this manner. I use the elastic bandage which I described many years ago for thigh amputations. The bandage is applied so as to retain as much blood as possible in the body."

The Doctor used a broad bandage of about two inches in width for the tourniquet instead of the narrow tubing generally used in this country. It took twelve seconds for him to make the circular incision, 40 seconds to free the flesh from the bone, and thirteen seconds more to saw the bone—the amputation thus occupying a little over one minute, the seat chosen being the middle third of the thigh. While the vessels were being tied by Drs. Ashhurst and Wharton, the Doctor made a dissection of the tumor and said:

"We find here many cysts and much extravasated blood, both of which are very common in a giant-celled sarcoma. Part of the bone has become the walls of the cysts. The growth probably started in the inferior part of the femur and has completely destroyed the articulation and has also involved the upper part of the tibia. The thigh is broken just above the knee, as we can easily see by the great freedom of motion. We will now dissect the patella and lay it back, as in this manner the arrangement of the growth can most plainly be seen. I have had very many cases of this kind in which I have operated as I have done in this patient, and there has been no return of the disease. In some cases it is possible to amputate with the loss of only a teaspoonful of blood, but in the present case the vessels are all much enlarged and so we have had more bleeding than usual. I generally allow the tourniquet to remain on for five or six hours after the operation; but, of course, ligate the vessels and dress the part at once. Catgut ligatures are used. The periosteum is ligated as well as the sartorius muscle which, unless this be done, is liable to contract. I do not use a drainage tube but allow the angles of the wound to remain open, and at the end of four weeks they will usually be found nearly healed. I use 1 to 10 carbolic acid solution for the instruments except the knife, which is laid in alcohol. For washing the wound I use 1 to 5000 bichloride, as I have found that a 1 to 2000 solution will cause an eczema where the dressing comes in contact with the skin. I dress with sterilized gauze and gauze dipped in the bichloride solution. Wire, or preferably, catgut may be used for sutures. A little compression is used in applying the bandage, and I use a cushion of moss in place of cotton as it is more elastic and cheaper. I do not find it necessary to remove the first dressing for three or four weeks unless there be a rise of temperature, when the dressing is at once removed. Thanking you for your kind attention I will now say good-bye."

Examination of the Heart.

Dr. Pepper at his clinic on September 22, introduced Dr. Sansom, of London, the celebrated specialist on heart diseases, and asked him to show the students how he would make an examination of a patient while making his rounds in the London Hospital.

In making the examination of a patient suffering from heart disease the following method was employed:

A camel's hair brush, some olive oil, a pencil, or still better, a dermatograph, a pleximeter, a binaural and single-stethoscope are required. The pleximeter is **T** shaped, about one and a half inches in height, and made of hard rubber or glass. It is held to the chest with the index and middle fingers of the left hand and tapped with the middle finger of the right. The usual methods of investigation viz., inspection, palpation, percussion and auscultation are employed in the physical examination of the heart. The walls of the heart are outlined with the pleximeter and marked with the dermatograph. Percussion is then made just within the line where dulness is to be expected and just without the line where resonance is to be found. If any mistake has been made it is clearly demonstrated and the line can easily be corrected. The apex beat is located and marked A; other points of interest observed are marked with arbitrary letters. The lines are then moistened with olive oil, the sternal notch, clavicle and ribs being also touched with the oil; and a piece of ordinary copying paper is placed over the chest and gentle pressure is applied. The marks of the dermatograph together with the outline of the sternal notch, clavicle and ribs are thus accurately and completely transferred to the copying paper. The name and date are added and the paper is ready for future reference.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PHYSICIANS AS WITNESSES.

From time to time interesting questions arise in regard to the rights and duties of physicians when summoned as witnesses in a court of law, and unfortunately the status of physicians as witnesses is not clearly defined, or it is very imperfectly understood, in the United States. This is the more to be regretted, because it sometimes leads to contentions which are annoying to the courts and prejudicial to the standing of physicians in the community. A case in point has very recently occurred in Wilkes Barre, Pa., where a physician, being summoned by the Coroner to testify in regard to the circumstances attending the death of a woman who died when under his care, refused to present himself at the inquest because his witness-fee was not guaranteed or paid in advance, until an attachment was served upon him, and then declined to answer the question: "What were Mrs. Duningan's symptoms when you were first called to attend her?"

In a letter, which the physician in question was kind enough to write to the Editor of the REPORTER, in response to a request for information, he states that his reason for declining to answer this question was that the "reply required professional skill"; and to the Coroner he stated that he declined to answer as a physician before the witness-fees were paid or guaranteed.

The information which we have in regard to this case leads us to feel a great deal of sympathy with the physician, who seems to have suffered on previous occasions when he gave testimony, trusting that his fees would be paid afterward. We heartily wish that courts and persons exercising the right of summoning witnesses, would provide a proper remuneration for medical men who are called away from their professional duties to act as witnesses, and that the remuneration were always promptly paid. This is a simple question of justice, and all sensible men can agree in regard to it.

In a civil case a witness may, indeed, refuse to attend at the trial, unless his traveling expenses and at least one day's pay for attendance are tendered him. But the rule is different in criminal cases, because the Government has the right to call any citizen to testify, and he must go when called. The Government is both legally and morally bound to pay him finally, but the question of pay is a separate and distinct one, which does not affect the duty of a citizen to obey the summons of a court. These statements, as we have the best authority for saying, apply also to the subpœna of a Coroner.

But the Wilkes-Barre case involves another point. The position of the physician in refusing to testify, in this case, rests upon two assumptions: one, that an answer to a question in regard to the symptoms of his patient would place him in the category of "expert"

witnesses; and, the other that an expert witness has the right to demand payment for services differing from that accorded to ordinary witnesses.

The first assumption, we are sorry to say, we think is wrong; and we have little doubt that a court would decide that the use of the technical word "symptoms," in the question, was simply a convenient way of asking for facts which had been observed by the physician, and which he had no right to withhold, merely because his education fitted him to observe them intelligently and to describe them intelligibly. If this were not the case, we might imagine a mechanical engineer refusing to testify as to the behavior of an engine before it burst, or a civil engineer as to the appearance of a bridge shortly before it gave way. Courts of law have the right to summon the most competent witnesses of any occurrence under investigation; and special fitness to observe and describe these occurrences does not relieve any one from the duty of testifying all his knowledge of them.

The second assumption: that a witness, when asked a question, the correct answering of which requires peculiar knowledge, becomes an "expert witness," and has a right to demand treatment—especially in regard to remuneration—different from that accorded to witnesses in general, is one which we wish was tenable.

In the case of medical men, it ought to be true that, when called upon to testify in regard to matters requiring strictly professional skill, they would receive consideration suited to the position in which they are placed, and remuneration appropriate to the amount of special preparation required for instructing the court. But, as the law now stands, there is no provision for "expert" witnesses, and experts cannot secure any other than ordinary witness-fees, unless they are paid by the parties to any litigation. We may not like it; but this is the fact.

As the matter stands now, a physician who is summoned as a witness has no rights above any other kind of witness. When subpœnaed he must attend, and when questioned he must answer, unless, on appeal to the court, he is excused from answering. This fact should be known to all medical men, so that they may not assume a position which is sometimes annoying and irritating to the officers of justice, and which may prove embarrassing or dangerous to themselves.

Our sympathy is naturally with our professional brethren in regard to their position when called as witnesses. We know how trying this position often is. But we are fully convinced that no good can come of following our feelings against the law and the settled custom of the courts. The only way in which the position of medical witnesses in the United States can be improved is by appealing to the legislatures to define this position in a way more consistent with our ideas of what is right. Men who take the stand taken by the Wilkes-Barre physician may, by making martyrs of themselves, as some men have done, and as he seems willing to do, draw attention to the subject in a way which will result in changing the present treatment of medical witnesses; but at present it must be admitted, if we would not deceive ourselves, that the law does not recognize any class of witnesses that can make terms with a court, or refuse to attend or decline to testify when summoned in the ordinary way.

DR. WILLARD H. MORSE.

In the *Druggists Circular* for September, 1888, there was a long and circumstantial account of the arrest of Dr. Willard H. Morse, of Westfield, N. J., on the charge of using the U. S. mails for a fraudulent purpose. The article described how a trap was set to catch Dr. Morse, by getting him to make a false certificate of a chemical analysis of a certain commercial article, and how he seemed to fall in it. His arrest was accom-

plished throught the instrumentality of the well known Mr. Anthony Comstock. As it was first reported,—and the story was extensively published in the daily papers—the case seemed to be hard against Dr. Morse. As the latter has been a contributor to the columns of the REPORTER, an article of his appearing as late as September 1, 1888, we felt a natural interest in his case, and were glad to receive from him a letter, in which he assured us that the charge against him was false and that on Monday, Sept. 10, he was honorably acquitted, before U. S. Commissioner Keasbey, of Newark, and that the latter, and Mr. Comstock, and the Editors of the Druggists Circular were satisfied that he was innocent.

On receiving this letter, we wrote to the editors of the Druggists Circular, to ask if they were correctly reported. In reply, they wrote that the claim made to us by Dr. Morse was "false from beginning to end." This plain statement has been followed up by the publication in the *Druggists Circular* for October of a full account of the proceedings against Dr. Morse, and their issue. The result, according to this account, was very far from an honorable acquittal, and we regret to say that it leaves us under the impression that Dr. Morse fell into a trap which would not have caught an honest man.

We refer to this matter partly because our readers have a right to know when one who has been allowed to use the columns of the REPORTER seems unworthy of confidence, and partly because Dr. Morse has had the assurance to ask us to vindicate him to the readers of this journal. We think we deal fairly with him and our readers when we say that he now occupies a position which has every appearance of being that of an unscrupulous and dishonest man. If this is the result of misfortune, we are very sorry for him; if it is the result of deliberate wrong doing, we trust his present shame may direct him into more honorable paths in the future.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION AND THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

It is with some regret that we note the fact that the number of the *Journal of the American Medical Association* for September 22 contains a letter from an anonymous correspondent in London who speaks in terms of severe disparagement of the recent Congress of American Physicians and Surgeons, which has been so great a success and so creditable to the profession of this country. The Editor of the *Journal* might have spared his countrymen the bitterness and malevolence of this unjustifiable affront, and his error in laying it before the readers of the *Journal* is the more unfortunate in view of the paragraph which immediately followed it.

The *Journal of the American Medical Association* was not intended to be the organ of any man, or of any party, and the best friends of the Association cannot be pleased when it is used to pay off old grudges or to gratify personal vanity.

It is a pity that such an unpleasant thing should have to be said; but the occasion seems to call for it. The part of the letter to which we have referred is published in another place in this number of the REPORTER, and our readers may judge for themselves whether or not our strictures upon it are justifiable. We have little doubt, however, that the charges of dishonorable conduct made by this anonymous correspondent will be repelled with equal indignation on both sides of the Atlantic, and that it will be fortunate for his reputation if he succeeds in concealing his personality.

THE QUARTERLY COMPENDIUM OF MEDICAL SCIENCE.

We desire to call the attention of the readers of the REPORTER to the quarterly magazine published at this office. It is not a duplicate of the REPORTER, but an inde-

pendent publication, which contains select papers taken from other medical journals—chiefly of Europe—and translations, classified according to subjects, and carefully edited. It makes a summary of the progress of medicine for each year, and includes papers which are rather too long for quoting in the REPORTER, or for which we have no room in this journal.

It is impossible, in the REPORTER alone, to give our readers all the medical news we would like to, and the best we can do is to offer them, at a very low price, this supplement, which consists of four numbers a year, each containing about 150 large octavo pages handsomely printed and covered, and which is worth more than many books of the same size which are sold at a higher price.

We are just now sending out specimens to those of our subscribers who do not take the COMPENDIUM. In doing this we are sending as many as we can of the latest issues; but last year's issue is worth the price and whoever gets a copy of it may be sure that this year's is, and next year's will be, every way better. We hope to hear from many of our readers, and to have a large addition to the subscription list of the Quarterly Compendium.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION. Part Third; Medical Volume.

With this volume the United States Government brings to an end the unparalleled series of books, published under its authority, describing the medical and surgical experiences of the army of the United States during the civil war. Those who are familiar with the volumes which have preceded this one will understand that it is praised sufficiently when we say that it is a worthy successor to them. Its text is most judiciously arranged, and its illustrations are simply superb. It is a monument of the munificence of the Government, and of the skill and devotion of the Surgeons of the Army.

The labor involved in preparing and issuing such a work as this can never be fully appreciated by those who have not been engaged in it; but all can admire the result, and pay their tribute of respect to the industry and genius which have combined to produce a work which sheds so much lustre upon the medical department of the United States Army.

A CLINICAL ATLAS OF VENEREAL AND SKIN DISEASES. By ROBERT W. TAYLOR, A.M., M.D., Surgeon to Charity Hospital, New York, etc. Parts I and II. Philadelphia: Lea Brothers & Co., 1888. Price $2.50, each part.

This magnificent work which is to be completed in eight parts contains a large number of handsome colored plates representing a variety of conditions of the genitalia caused by venereal disease. Fortunately for mankind such appearances as are here shown are rarely seen outside of hospitals devoted to the care of the outcast or impoverished classes. Still, every student of venereal diseases ought to be familiar with them, and to those who have had the benefit of hospital experience or observation which included such sights as this work represents, its plates will serve as a powerful reminder of what they have seen before, while those who have had no such observation will find here uncommonly graphic and faithful representations of them.

In a work of this sort the text must be, to a certain extent, subordinated to the pictures. Its methods are more like those of the clinic than those of the lecture-room. But it is none the less instructive for this fact, and on this very account it is more interesting than a formal treatise could be. The reputation of the author as a syphilographer assures the reader that he may trust the scientific statements it contains, and the artistic excellence of the plates speaks for itself.

THERAPEUTICS: ITS PRINCIPLES AND PRACTICE. By H. C. WOOD, M.D., LL.D., Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System in the University of Pennsylvania. Seventh edition. 8vo, pp. 908. Philadelphia: J. B. Lippincott Co., 1888. Price: cloth, $6 00; sheep, $6 50.

When Dr. Wood first issued his work on Therapeutics it immediately took a very high rank in the estimation of the profession, and this rank has been maintained as it has passed through its various editions, until now there is little need for praising what is already so well known. No work in the English language contains so complete an account of the physiological action of drugs, and none contains a more intelligent account of the way in which drugs should be used.

This last edition has all the merits of its predecessors, and more. It has been thoroughly revised so that it includes the most recent additions to the list of medicaments, and it has been rearranged so as to make its information more easily accessible to active practitioners. We can heartily recommend it to the notice of our readers, and congratulate the author upon its contents, and the publishers upon the way in which it is issued from the press.

THE APPLIED ANATOMY OF THE NERVOUS SYSTEM. By AMBROSE L. RANNEY, A.M., M.D., Professor of the Anatomy and Physiology of the Nervous System in the New York Post-Graduate Medical School and Hospital, etc. Second edition. 8vo, pp. xxxv, 791. New York: D. Appleton & Co., 1888. Price $5 00.

Dr. Ranney's book gives a very complete description of the different parts of the brain, spinal cord

and nerves, both in regard to their anatomy and physiology and in regard to their various pathological conditions. The portion of his work devoted to cerebral localization, and to the course of the different nerve tracts in the cord and brain, are especially full and instructive. A work of this kind is a necessary part of the library of every neurologist, and would be a valuable addition to any library. Nowadays the work of the surgeon is so often applied to the treatment of diseases of the nerves and spinal cord and brain that surgeons need to know a great deal which was once considered to be entirely within the province of the neurologists. To such surgeons as appreciate this need we can heartily recommend Dr. Ranney's book, the text of which is clear and intelligible, and the illustrations of which are admirable.

Finally, it may be stated that the book is very handsomely printed and well bound, and that it reflects as great credit upon the publishers as upon the author.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

Memoir of A. F. Erich. By George H. Rohé, M.D., Baltimore, Md. 15 pages. 1888.

On the Treatment of Acute Rheumatism with Special Reference to the Use of the Salicylates. By Donald W. C. Hood, M.D., London, England. 66 pages.

—Dr. Rohé, at the request of the Faculty of the College of Physicians and Surgeons of Baltimore, prepared this Memorial Address on the life and labors of his fellow-professor Dr. A. F. Erich. Its style is admirable, and it presents a sketch of Dr. Erich's life worthy of the careful attention of all who admire what is excellent. As the tribute of a friend it is full of warmth, and as a study of character it is marked by great discrimination and judgment.

—Dr. Hood's pamphlet, to which we have already called attention in an editorial in the Reporter, May 26, 1888, contains a most elaborate and interesting study of the treatment of acute rheumatism, and especially of the effects of the salicylate of soda. He is a strong advocate of the use of this drug in acute rheumatism; but he is a discreet and temperate advocate, who discriminates between the different conditions which different cases may present. It would be of advantage to all thoughtful medical men to learn what Dr. Hood has to say on the subject he here discusses; for there is much in his paper beside the mere study on therapeutics indicated by its title.

—Dr. William Osler, Professor of Clinical Medicine in the University of Pennsylvania, has been appointed Physician to the Johns Hopkins Hospital, and Professor of Medicine in the Johns Hopkins University, Baltimore. Dr. Osler took his degree in McGill University, Montreal. He subsequently studied in London, Berlin and Vienna, and in 1885 was appointed Gulstonian Lecturer for that year before the Royal College of Physicians, London; and in 1886 he delivered the Cartwright Lectures in New York.

Correspondence.

The Toxicity of Fruit Juices.

To the Editor.

Sir: In these days when we are told that poisonous germs are concealed in every gutter when we are abroad; when in a room in our own homes the air may be freighted from a badly constructed system of drainage or by overcrowded rooms; and when, even in the country, we may be drinking impure water from a sparkling spring—I say, when we have these and many other just causes for true alarm, it is little less than a sin to trifle with people's credulity or resort to unfair means to advertise one's self by misrepresentation. No class of people is more open to criticism than is the apothecary. He is attacked on one side by those who say he adulterates; on the other by those who think he charges them exorbitant prices. The latest specimen of the former class is the "Toxicity of Fruit Juices" crank, who insists that nearly all the syrups the thousands of people in this country are daily consuming are artificial, and that those who use them are not only wilfully cheated, but also given poisons which are calculated to impair their very vitality by slow degrees. This charge is a base slander; and one must be a fool to think the majority of people would believe it. The better class of drug stores all over the country use natural fruit juices: just as the better confectioners flavor their goods with natural fruit juices or extracts made from them. Almost any one can distinguish an artificial fruit juice from a natural one, and I venture to say there is not one drug store in fifty—taken promiscuously—that would sell artificial syrups. While an apprentice in the drug business, and within a few years after, I was in seven different stores, two of these at the seashore, and during that time I have handled hundreds of gallons of fruit juices, and I have never sold a single artificial fruit syrup nor heard of a respectable druggist who has done so.

A great many apothecaries express their own juices, while the majority buy them of reputable manufacturers, who make them on a large scale more cheaply than they can be made in a small way. So great has this industry become within the last few years that these manufacturers contract a long time ahead to take a fruit-grower's whole crop; and any one who will take the trouble to look the matter up can easily be convinced of the great amount of fruit used for this purpose.

Why any man should make such false charges as were made in an article on the Toxicity of Fruit Juices, in the REPORTER, Sept. 1, p. 267, 1888, is beyond my power to understand. If he has erred from ignorance, I hope you will use this means to correct his false statement; if he has deliberately stated what he knew to be untrue in order to advertise a very "shaky" means of existing—that of pretending to be an analyst, when he has no right to the name—it is high time that his pretensions were exposed, and he himself shown in his true light, whatever it may be.

Yours truly,

Philadelphia, September 29, 1888. CORNELIUS W. STRYKER.

NOTES AND COMMENTS.

Carping Criticism.

The *Journal of the American Medical Association*, Sept. 22, contains an unsigned letter from an "occasional correspondent" in London, which concludes as follows:—"The meeting this month, in Washington, of the Congress of American Physicians and Surgeons, has made little or no impression upon the mass of medical men throughout Europe. Now and then I have heard reference made to the meeting in a kindly manner in this and other medical centres. A very large number of eminent members of the profession in all parts of Europe have been invited, and even urged, to attend, and but few, very few, will be at the meeting, even though, I am told, *suggestions have been made to many that possibly American degrees may be conferred upon many who will honor them by their presence.* [Italics ours.] Unfortunately for the present managers of the Congress, the part they have taken during the past year against their own countrymen has now become more apparent here, and the reaction has been anything but favorable to them and their meeting. The suggestion, or even the promise, of degrees to be given out, which is whispered around here, may induce a few to attend the meeting, but the very many invited will stay at home.

"I cannot close this brief letter without making reference to the second visit to the late meeting of the British Medical Association, of the Father of the American Medical Association. Dr. Davis was received not only warmly, but enthusiastically, and all honor was shown the late President of the Ninth International Medical Congress."

Irish Lunatic Asylums.

From the thirty-seventh annual report recently issued, it appears that at the close of last year the insane in Ireland had increased by 561 as compared with the preceding year. This increase occurred among the lunatics in public asylums, poorhouses, and in private institutions, and is considerably more than in any previous like period. The admissions into district asylums for the year numbered 2863, which, with those previously admitted, make a total of 12,940 under treatment, of whom no less than 620 were relapsed cases, some for a fourth and fifth time, and not a few at regular intervals—facts indicative of the recurrence of mental disease. Of these 12,940 inmates, 1582 were discharged; of whom 1123 had recovered, 375 were relieved, and in 84 instances no improvement had taken place. The mortality amounted to 857, or a death-rate of not quite 7 per cent. on the total treated.

With respect to the curative and beneficial results of treatment during last year, the former, if compared with admissions alone, would show a return of nearly 40 per cent.; but on the average under treatment, the cures would stand at about 11 per cent., and the improved at nearly 4 per cent. As regards the relative proportion of the probably curable to the incurable, they stand in the ratio of 1880 of the former to 8619 of the latter, in which are included, to the number of 827, epileptics, lunatics, and idiots. The average capitation cost on the daily average of inmates amounted to about one hundred dollars.—*Lancet*, August 18, 1888.

Antimony in Acute Rheumatism.

For acute rheumatism, so long as it affects the joints only, Professor Jaccoud (*Journal de Médecine de Paris*, May 6, 1888) is quite satisfied with the treatment with salicylate of sodium. But when the pain has gone, and nevertheless maintenance of the high temperature or the development of hyperpyrexia shows some complication at work, he thinks the use of the salicylate of no avail or even harmful, and resorts to a treatment by a depressant, viz., tartar emetic, pushed to an amount which produces vomiting. In cases which occupy an intermediate position—in which under the salicylate treatment the pain ceases, but the temperature is only slightly reduced—he employs hydrobromate of quinine in doses of about four grains every six hours. —*Practitioner*, July, 1888.

Honors for Women Doctors.

The French Government has just distinguished itself by conferring the officership of the Academy on Madame Gaches-Sarrante, the doctor to the Grand Opera of Paris, for "exceptional services." What the exceptional services consisted in we are not told, but the woman's career is one worth noting as an instance of what indomitable perseverance, assisted by sterling qualities, can effect in the long run. Married at sixteen, and a widow at eighteen years of age, she experienced the necessity of providing for the requirements of every-day existence. An accomplished musician, and gifted with a voice of excellent quality, she played in operettas for some time until an affection of the larynx cut her theatrical career short. During a visit to Montpellier, yielding probably to the influence of environment in a town where two out of every twenty people are doctors, she studied for and obtained the diploma of midwife. A year or two later her taste for this new occupation stimulated her into working for the diploma of *officier de santé*, and later on, undeterred by the six years' curriculum and the preliminary degrees in arts and sciences, she resolutely carried the doctorate by assault. Then she came to Paris, and one fine morning was appointed *médecin de l'opéra*, a much envied, if not very remunerative position. Our neighbors have evidently surmounted those prejudices which still limit the ambition of women practitioners in this country.—*Medical Press and Circular*, August 15, 1888.

New Preserving Fluid.

At the meeting of the New York Pathological Society, June 13, 1888, Dr. T. M. Prudden presented the formula for a new preserving fluid, which had been referred to by Dr. Northrup.

Water	35 fl. oz.
Common salt	3 oz.
Saltpetre	6½ drachms
Carbolic acid	1¼ fl. "
Glycerine	4 fl. "
Amylic alcohol	1¾ fl. oz.
(or Ethylic alcohol	3½ fl. oz.

Specimens should be first soaked in a strong brine and then placed in a large quantity of this fluid. He believed the mixture would be found to serve a useful purpose in the temporary preservation of gross pathological specimens without changing their color or otherwise altering their general appearance. The mucous membranes were particularly well preserved in the fluid.—*Medical Record*, August 4, 1888.

NEWS.

—The number of cases of yellow fever at Jacksonville is decreasing.

—The Medical Society of Virginia will meet in Norfolk, October 23.

—The number of registered physicians in New York City is said to be 2350.

—Sir William MacCormac did a suprapubic lithotomy at the University Hospital, Sept. 26.

—The first Congress of Italian physicians will be held in Rome from October 15 to 18, 1888.

—The 75th annual meeting of the Vermont State Medical Society was held at Montpelier, October 11 and 12.

—Professor Bardenhauer, of Jena, is to be offered the Professorship of Physiology in the University of Greifswald, made vacant by Professor Budge's death.

—Dr. H. Frémy has been instructed by the French Government to visit the United States to study the methods of treatment of tuberculosis in hospital and in private practice.

—The corner-stone of a hospital, to be an annex to the present city hospital in Baltimore, under the control of the Sisters of Mercy, was laid September 30 by Cardinal Gibbons.

—Dr. Louis Bauer, of St. Louis, is said by the *International Medical and Surgical Synopsis*, September, 1888, to be convalescing from a remarkable combination of disorders, apparently the result of wound-infection.

—Succinamide of mercury is the latest claimant for favor in the hypodermic administration of mercury. It occurs in the form of a white, silky powder, very soluble in water. The watery solution is said to remain clear a long time, and to possess the additional advantage of not precipitating albumin held in solution in liquids; it gives no precipitate with serum from the pleura, and none with hydrocele fluid.

—The *Lancet*, Sept. 29, 1888, says that the Minister of Education has made the following appointments in the University of Vienna, ignoring the selections of the professorial Senate, which he considers were dictated by motives of personal liking rather than of public utility: Professor Emil Zuckerkandl, of Graz, to the chair of Anatomy; Professor V. Ritter von Ebner, of Graz, to the chair of Histology; and Professor

Theodor Puschmann, of Vienna, to the chair of the History of Medicine.

—On September 25, a Memphis physician was summoned to a patient who had just returned from Decatur, where yellow fever existed. He had many of the symptoms of that disease. It was subsequently determined, however, that the patient with the suspicious symptoms was intoxicated, and that the symptoms were due to an accompanying "bilious" attack. In the meantime the populace had become frantic with fear; and when they learned that there was no cause for alarm, they gave vent to many expressions by no means complimentary to the attending physician. These the *Memphis Medical Monthly*, October, 1888, publishes under some introductory remarks upon "man's inhumanity to man."

HUMOR.

Citizen. "Hello, Doc., have you seen Mike?" Doctor. "What Mike?" Citizen. "Microbe. He's looking for you."—*Memphis Medical Monthly.*

Comparative Appetites.—Very stout old lady (watching the lions fed): "'Pears to me, Mister, that ain't a very big piece o' meat fer seech an animal." Attendant (with the greatest and most stupendous show of politeness on earth): "I s'pose it does seem like a small piece of meat to you, ma'am, but it's enough for the lion."—*Life.*

Overtaxing His Brain.—Old Mrs. Bently—"Did you hear, Josiah, that the young student who has been boardin' at the Hendrickses is very sick?" Old Mr. Bently—"Yes, I heerd so; what's the trouble with him?" Old Mrs. Bently—"Studyin' too hard, I s'pose. The doctor says he's got information of the brain."—*The Epoch.*

Prepared for the Ordeal.—Boggs: "Hello, Jagley! What on earth are you doing with that box under your arm?" Jagley: "Sh! It's a phonograph. I'm going to call on a young lady from Boston this evening, and this thing, with the help of a dictionary, will enable me to study out what she says at my leisure, after I get home."—*Judge.*

That Altered the Case.—Dr. Pillsbury (to patient): "My dear sir, all you need is plenty of outdoor exercise. Now, here is a little work that I would strongly advise you to read. It will teach you how to gain and preserve health. Its title is 'Physical Culture for the Million,' and—" Patient: "But, doctor—" Dr. Pillsbury: "Well?" Patient: "I wrote that book."—*Time.*

A Disconsolate Wife.—"I don't believe in these secret societies," said one Austin lady to another. "That's very singular," replied the other; "your husband is a Forester, a Knight of Pythias and a Knight of Honor, and you will have at least $10,000 when he dies." "But what good does all that do me," was the tearful response, "when he never dies?" and the poor creature burst into tears.—*Texas Siftings.*

Science and Fleas.—In answer to a correspondent who desired to know how to drive fleas out of a room, the Philadelphia *Press* says: Science has recently discovered that the muscles, or springs in a flea's legs, enable it to jump a distance equal to 200 times its length. If, therefore, you will place the fleas in a straight line, at a distance equal to 200 times their length, from an open door, and can train them to make the jump all together in the right direction, you may perhaps be able to secure their absence. Failing in this, consult a druggist.

OBITUARY.

CLARENCE G. HOLLISTER, M.D.

Dr. Clarence G. Hollister, who has on several occasions made valuable contributions to the columns of the Medical and Surgical Reporter, died September 27, 1888, at his residence in Meadville, Pa., after a five weeks' illness with pneumonia.

Dr. Hollister was born at Garrettsville, O., about thirty-four years ago. He was educated at Wooster Medical University at Cleveland, and after graduating from that institution practiced his profession for a time at Sharpsville, Mercer County, Pa. He afterward removed to Cambridgeboro, and settled down to hard work in that place. He was young and energetic, and his capacity for work seemed to have no limit. Unfortunately his strength was overestimated, and his health was undermined by the severe and constant strain. In December, 1882, Dr. Hollister married Frances, widow of the late W. R. Gill.

About one year ago Dr. Hollister located in Meadville, and he was fast building up a lucrative practice when he was stricken with the fatal illness and was compelled to relinquish all work. He was a pure and upright man in every sense of the term, and all who had the pleasure of his acquaintance will regret to learn that he is no more.

SOLUTION FERROUS MALATE.

(Amer. Phar. M'f'g Co.) 4 Grs. to Fluid Drachm.

DOSE —30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat, and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

Solution-Salicylate of Iron

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful four times a day.

An unfailing remedy in acute or chronic Rheumatism, where deformity has not yet resulted. Has also been prescribed with great satisfaction in other affections where Salicylic Acid, Bi-carb. Sodium and Ferrous Malate are indicated.

Ferrous Malate, Gentian & Cinchona

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron. Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

RECORD OF ONE TERM OF SERVICE IN THE SURGICAL WARDS OF THE GERMAN HOSPITAL OF PHILADELPHIA.

BY J. WILLIAM WHITE, M.D.,
ONE OF THE SURGEONS TO THE HOSPITAL.

I desire to place on record, in as brief and concise a manner as possible, the most important of a series of cases treated by me during a term of service at the German Hospital, extending from the first of February to the middle of May, 1888. I do this because many of the cases are in themselves interesting and instructive, but especially with the wish of bringing before the profession through the columns of this journal the varied and extensive character of the surgical service in this hospital. I shall classify the cases rudely and confine myself to the most salient points, avoiding detail.

Modified Pirogoff Amputation. P. D., 11 years old, while riding on the platform of a passenger train was thrown off, and fell with his left foot under the wheels, sustaining a severe crushing injury of all the anterior portion of the foot, which necessitated amputation. As the tissues of the heel had escaped injury, I performed a Pirogoff operation omitting, however, the section of the lower end of the tibia and fibula, and placing the sawn surface of the os calcis in contact with the articular surface of the tibia, the former bone fitting closely between the external and internal malleoli. Cat-gut drainage was used through the posterior angles of the wound, and a small rubber drainage tube laid across its anterior portion. On the evening of the third day the temperature reached 101.5°. The stump was dressed and found in good condition. There had been but moderate oozing, and no retention of discharge. Next morning the temperature was normal, and so remained. Two weeks later the stump was again dressed, the drainage tube removed and the dressing reapplied. At this time there was slight motion of the os calcis upon the tibia, but the position was perfect. The stump was carefully dressed and, the sutures having been removed, it was allowed to remain without further inspection for three weeks, consolidation in such cases taking place more slowly than when two sawn surfaces are applied to each other. On removing the dressing at the end of this time the bones were found perfectly united, but the os calcis had a slight angle with the bones of the leg. Measurements on each side from the anterior superior spinous process to the lower surface of the heel were precisely the same, and the little patient could walk without pain and almost without a limp. The union was so firm and the practical results so good that I made no attempt to straighten the angle which I have mentioned.

This case illustrates the excellent results which can be obtained by the modified Pirogoff operation when it is possible to insert the piece of calcaneum in the lower flap between the malleoli, the latter giving admirable support and preventing displacement either inward or outward. The opening of a second extensive surface of cancellated tissue—at the lower end of the tibia—is thus avoided, and this is worthy of consideration, though not of so much impor-

tance now as in the days when antiseptics were unheard of. The case also illustrates, however, one of the minor disadvantages of infrequent dressings. The slight motion which existed, at the time of the second dressing, permitted subsequent displacement; this remained unnoticed during the long period that elapsed before the next dressing, as it was not sufficiently marked to be observed through the bandages. The use of a splint would have made displacement impossible, and I shall either change the dressings oftener in my next case or employ a felt splint moulded to the posterior surface of the stump and ankle.

Resection of Ankle. R. D., 25 years old, while working in the Pencoyd Iron Works, sustained a compound luxation of the ankle joint, produced by a heavy bar of iron falling upon his foot. The internal malleolus was fractured on a level with the articulating surface of the tibia; the fibula was fractured two inches from the lower extremity; the soft parts were widely torn, and several inches of the tibia protruded from the wound. The vessels, with the exception of the dorsalis pedis, were intact, and the anterior portion of the foot in good condition. I enlarged the opening through which the tibia protruded and removed the internal malleolus, together with the lower extremity of the tibia. The lower fragment of the fibula was removed through a curved incision parallel with the posterior border of the external malleolus. I then with a Hey's saw removed the upper surface of the astragalus, brought it up firmly against the lower end of the tibia, placed two small rubber drainage tubes in position, one behind and one in front of the line of the union of the bones, brought the external wound together with silver sutures and put the whole foot and leg in a plaster-of-Paris dressing, leaving fenestra for the discharges to escape. In five weeks union was perfect with the exception of a small patch of granulations from the inner angle of the wound. The highest temperature was reached on the evening of the seventh day, when it touched 101°. At this time the first dressing took place; subsequently the temperature continued to be absolutely normal.

In cases of which this is an illustration, the plaster-of-Paris splint is most admirable for the absolute fixation and immobility which it affords. When, however, on account of the soaking of the discharge it becomes necessary to remove the splint, it is very difficult to do so without considerable disturbance of the part. This, after excisions, is very objectionable, and I shall feel disposed at my next operation of the character just described to depend either upon the silicate dressing, which is more easily cut, or upon felt splints moulded to the limb.

Amputation at the Lower Third of the Leg. This was done in two cases, both of crushing injury received upon the railroad, one in a boy 10 years old, the other in a woman 60 years old. Both patients recovered without elevation of temperature, the highest in either case being 100.8°, and that on only one occasion.

Amputation of First, Second, and Third Metacarpal Bones and their Corresponding Fingers. This case was one of crushing injury of the hand from compression under the shaft of an engine. With a little difficulty, enough of the soft parts were preserved to make flaps for the thumb and little finger, leaving a "lobster hand" which, however, proved to be very useful. There were only three dressings; no elevation of temperature.

Amputation at the Wrist Joint. In this case the entire hand was crushed between the bumpers of cars. The amputation was done at the wrist-joint, the styloid processes of the ulna and radius being retained. Union took place by first intention with only four dressings; there was no elevation of temperature. The stump was a useful and symmetrical one, and the amount of pronation and supination retained somewhat remarkable. Unless the styloid processes interfere with the application of an artificial hand (and I see no reason why they should), it would seem useless to remove them in this amputation, although the usual advice is to do so.

Amputation of the Arm. In a case of railroad injury crushing the fore-arm, elbow, and lower arm, I amputated at the upper third by the musculo-cutaneous flap method. The soft parts were brought together in layers, the biceps and the brachialis anticus being first stitched to the triceps and then the skin brought together over the muscles by a separate row of sutures. I preserved some doubtful tissue in my desire to avoid going to the shoulder joint in this case, and as the result there was slight sloughing of the skin flaps, the temperature rising on one occasion to 103°. With that exception there was no complication, and the patient recovered promptly with a symmetrical and useful stump.

Abdominal Section. *Case I.* — Miss E. L., 38 years old, with a family history of tuberculosis, was well until she was 20 years of age when she met with an accident producing a severe contusion of the left ovarian region. This was followed by great tenderness, which persisted for a long period. Menstruation became very scanty, irregular, and exceedingly painful. Two years ago, after an acute exacerbation of the ovarian symptoms, there was a sudden and copious discharge of pus from the vagina, followed by temporary relief. Since then she has had symptoms of pelvic cellulitis, accompanied with pain in the right ovarian region, tenderness, and frequent discharge of pus. Oöphorectomy was performed May 8, and five weeks later she expressed herself as freer from pain than she had been for years. Recovery was rapid and interrupted only by the formation of a small stitch-abscess requiring evacuation. This kept the temperature for a few days in the neighborhood of 100°; during the rest of the time it was normal.

Case II.—Mrs. E. B., 34 years old, presented herself with a large abdominal swelling, which had begun about one year before. It first appeared on the left side, afterward extending to the right; the pain in the early stages was extremely severe but decreased as the tumor enlarged. The diagnosis of pregnancy was persisted in by a local physician up to the time of her admission to the hospital. I performed abdominal section on April 10, removing a multilocular cyst of the left ovary, which weighed, with its contents, about twenty pounds. As there was a small fibroid growth of the uterus, and as she had not yet reached her menopause, I removed the uterine appendages on the right side also. The second day after the operation her temperature reached 100.5°; with that exception it remained normal. There was but one dressing; she was kept in bed for three weeks as a matter of precaution, and was discharged as cured.

Case III.—Mrs. S., 45 years old. She had a family history of cancer and tubercule. She had married when 16 years old, had nine children—twins once and triplets once, and had had four abortions. There was a laceration both of the cervix uteri and of the perineum. The patient had suffered much from dysmenorrhœa and menorrhagia, had had gout affecting the great toes in 1882, and later in the year an attack of right-sided hemiplegia, from which she slowly recovered. For some time past her chief difficulty had been from profuse and uncontrollable menorrhagia, accompanied with great pelvic and ovarian pain. Oöphorectomy was performed April 23; the patient recovered without a complication and left the hospital free from all symptoms.

Case IV.—Mrs. B., was admitted Feb. 3 with a large abdominal swelling, which had been twice tapped in the median line for what the physicians in attendance pronounced a multilocular ovarian cyst. An examination under ether rendered this diagnosis exceedingly doubtful in my opinion and in that of some of my colleagues. I determined, however, with their approval, to operate partly for the sake of exploration and partly to furnish drainage for the intraperitoneal exudation. It was found on opening the belly, that the case was one of encysted peritonitis. During the operation a second large cyst, not opened by the original incision, broke down under my finger and discharged a large quantity of turbid fluid.

A glass drainage tube was used, the peritoneal cavity irrigated with a warm boracic acid solution, and the wound sewed up. She did well for four or five days, but then died suddenly from a rapid extension of the peritonitis.

Herniotomy—Radical Cure. *Case I.* —G. B., a farmer 49 years old, was admitted March 27 with a large swelling which occupied the right half of the scrotum; it was pear-shaped in form and was divided about mid-way between the fundus or base of the swelling and the line of Poupart's ligament by a transverse groove. The diagnosis of complete oblique inguinal hernia constricted in the sac was made without difficulty, the symptoms—constipation, vomiting, etc., all pointing unmistakably in this direction. Herniotomy was performed, in regard to which the following interesting points may be noted.

1. The strangulation was in the sac itself, was due to the contraction of bands of lymph, and was exceedingly tight, so that with safety to the closely adherent bowel it was impossible to get the tip of a director beneath it. It was divided from without inward with delicate touches of the knife. As a consequence of the position of the constriction, the bowel contained in the upper half of the swelling—the part occupying the canal and the region of the external ring, was considerably swollen, reversing the usual shape of hernial swellings in having the larger portion above. The rings and canal were found largely stretched, and at these points the bowel was perfectly free.

In the neighborhood of the contraction there were numerous adhesions between the bowel and the sac.

2. The knuckles of gut below the constriction were found to be black, cold, offensive in odor, and crepitating when handled. It did not seem possible at first sight that they could recover themselves, but a half-hour's delay, during which time they were allowed to rest upon the upper surface of the thigh covered with hot carbolized towels, so improved their condition in every respect that it was deemed safe to return them to the abdomen.

3. The sac contained an exceedingly large quantity of fluid. Within the sac was found a body about the size of the last joint of the thumb, glandular in structure and with a fleshy rounded cord running up from it through the inguinal canal. This cord contained a hard wire-like body which slipped from between the fingers when handled. At first the fluid was thought to be that of a hydrocele and the glandular body to be an atrophied testicle with the accompanying spermatic cord and vas deferens In other words, it was thought that the hernia was of the congenital variety. A little further investigation, however, revealed both testicles *in situ*, and a more careful examination showed that the gland was one of the mesenteric group; the supposed vas deferens proved to be an enlarged hardened lymphatic vessel, and the fleshy mass surrounding it a portion of omentum which had been much altered through its long sojourn outside of the abdomen. The hernia had been irreducible for years.

4. After the removal of this piece of omentum and ligation of the neck of the sac, the sac itself was excised. The fundus of the sac, which was tightly adherent to all the scrotal tissues, was left in place. The different layers of the abdominal wall on each side of the wound were first stitched together with cat-gut, and then the two broad fleshy walls thus obtained were united by silver sutures, cat-gut drainage being used. The lower third of the wound was left open and was packed with strips of iodoform gauze. The patient recovered; only a few drops of pus formed, the temperature was normal after the second day, only three dressings were necessary, and the hernia was cured (?). Three months later there had been no return.

Case II.—T. B., a man 19 years old, was admitted May 5 with a strangulated hernia of the right side, complicated with a retained testicle. The hernia was of the congenital variety, attacks of strangulation were frequent, and the presence of the testicle in the canal rendered the use of a truss almost impossible. The testicle was found atrophied, and was therefore removed. The sac was ligated and excised and the wound treated as in the case just described with the exception that as the whole sac was removed no portion of the wound was left open. Union occurred by first intention—no fever, no pus. Apparent cure two months after the operation.

Concussion of the Brain—Cerebral Localization. J. Mc., a man 45 years old, a laborer, was admitted May 3, in a semi-unconscious condition; there was a history of his having fallen sixteen or eighteen feet from a tree, striking upon his head. There was a slight ecchymosis in the left temporal region.

A horse-shoe shaped flap of the scalp was raised for exploratory purposes. No depression or other evidence of fracture of the skull could be detected, and the flap was replaced. The patient had at that time all the characteristic symptoms of concussion of the brain, together with complete aphasia. When disturbed, he moved all his limbs in the effort to return to the position which he preferred, which was that characteristic of cases of concussion—a lateral decubitus with the legs flexed on the thighs, and the thighs on the abdomen. In about forty-eight hours it was observed that his right leg became motionless and helpless, and in the course of two days more he ceased to use his right upper extremity and no voluntary movement in it could be elicited. I then thought the case was one of rupture of one of the smaller posterior branches of the middle meningeal artery, either from fracture of the internal table, or from the direct result of the injury. The symptoms pointed to a slowly forming clot, creeping upward along the Rolandic line and involving successively the centres for speech, for the lower limb, and for the upper limb. I called a consultation of my colleagues for the following day with the intention of trephining. By the time we met, however, he had begun again to move the right arm and it was decided to wait and watch developments. In a day or two more movement returned in the right leg and before the end of the week he for the first time answered questions and spoke now and then spontaneously. He steadily improved in all respects passing, however, through a period of dementia, during which time he was filthy in his personal habits and occasionally destructive, breaking up his

furniture in order to obtain pieces of wood to chew, etc. After recovering sufficiently to be of use about the hospital, he absconded, though still in a condition of feeble intellect.

Compression of the Brain; Cerebral Localization. A. B., a man about 60 years of age, was admitted in the afternoon of March 14, having also fallen from a tree, striking upon the side of the head. He was unconscious, with all of the symptoms of compression of the brain. There was a scalp wound, which, upon being slightly enlarged led down to sound bone. It was situated behind the parietal protuberance. The only paralysis which was noticeable was facial. As it was clearly a case for trephining, or at least for exploring the skull with that object in view, and as the existing scalp wound threw no light upon the condition, I carefully mapped out upon the scalp the area indicated by the facial palsy and punctured the scalp with a bistoury to indicate the precise point at which I expected to find the brain lesion. A large flap was then raised, and within one-eighth of an inch of my puncture was found a splintered fracture of the skull, with laceration of the brain substance. After beginning the removal of the fragments, the fracture was found to have extended through the inner table in the whole temporal region. The meningeal artery had been wounded and required ligature; the line of fracture extended to the floor of the middle cerebral fossa, but the only point at which brain substance had been actually wounded was at the locality mentioned. The patient never recovered consciousness, but died within a few hours of shock.

Shoulder-Joint Amputation. A. B., 28 years old, was run over by a train which crushed his entire right arm to within a few inches of the shoulder. The hemorrhage had been great, and on his admission he was severely shocked and almost bloodless, showing very little disposition to react. I decided, however, to give him the chance and performed a shoulder-joint amputation, keeping him alive while so-doing by elevation of the extremities, dropping the head over the edge of the bed and using hypodermics of ether, whiskey, and digitalis, and of hot saline solutions. He appeared to re-act very well for an hour or two, and then died suddenly of heart failure. I have regretted since that I did not transfuse directly into a vein, employing either blood, or a saline solution; I shall certainly do so in the next similar case I have.

Excision of the Knee; Dog Bone Peg used. S. C., 22 years old, with a family and personal history of tuberculosis, was admitted to the hospital on May 18, for chronic arthritis of the knee-joint. As immobilization produced no favorable change I performed excision some weeks later, removing a section of the tibia and femur and carefully scraping out the carious cavities which I found in both bones. In bringing them together I used as a bond of union the metacarpal bone of a dog. This had been freshly removed with all antiseptic precautions. It answered very well mechanically, keeping the bones in excellent position; but it was, so far as I could see, of no other special advantage. (This case is reported in detail with remarks on the general principles of bony union, in the *Lancet*, August 18, 1888.)

Bullet Wound. E. D., 23 years old, was admitted March 28 with a bullet wound situated just to the left of the symphysis pubis. After a little search the ball was found to have taken an upward direction and to have lodged in the scrotal tissues just below and in front of the bulbous portion of the urethra. It was extracted by a dissection which bi-sected the lower portion of the scrotum. The urethra was not opened. Cat-gut drainage was used and recovery was uninterrupted.

Transverse Fracture of the Patella. The Aseptic Use of Malgaigne's Hooks. E. H., 30 years old, fell while getting on a train which was in motion, and in the attempt to save himself sustained a transverse fracture of the patella, through muscular action. It was immediately followed by great swelling of the joint and entire disability. A few hours later, with the most careful antiseptic precautions the joint was aspirated, several ounces of bloody fluid being removed; I then brought the bones together from a separation of more than three inches, using Malgaigne's hooks and passing them directly through the soft parts. Irrigation with bichloride was kept up during the operation and the knee was dressed antiseptically, the hooks being included in the dressings. There was no elevation of temperature, and but two dressings in five weeks. At the end of that time the hooks were removed, the line of apparent union between the fragments being scarcely perceptible. The vertical diameter of the patella was the same in both limbs. A posterior splint with the figure-of-eight bandage was applied, and the patient cautioned against undue movement. He, however, kicked around freely in bed and some-

what displaced his dressings, and a few days later I found a separation of the fragments to the extent of perhaps three-eighths of an inch. He was again placed on a posterior splint with a firm figure of eight bandage. He recovered with good fibrous union, and no further separation of the fragments.

Vesical Calculus; Secondary Pyonephrosis. J. P., 30 years old, was admitted April 3 with a history of long standing vesical calculus. This history was easily confirmed on examination, when I found that the stone was probably of extremely large size, and therefore decided upon the suprapubic operation, to which the patient consented. He was extremely weak and had a profuse dysenteric diarrhœa. The night before the day fixed for the operation, he suddenly died and the autopsy, which I conducted the following afternoon, showed a condition of the kidney which made it marvelous that he had lived so long. The entire secreting structure had disappeared and the organs were transformed into multilocular sacs containing enormous quantities of muco-pus. The ureters were dilated to almost the calibre of the small intestine. The bladder contained a calculus weighing 532 grains. The origin of this dilatation of the ureters and kidney in such cases is of great interest, as no appreciable obstacle to the entrance of urine into the bladder is usually discoverable. It seems probable that in some instances the dilatation is brought about by the frequent contraction of the walls of the bladder, each act of this character temporarily interrupting the flow of urine through the vesical end of the ureter. This, taken in conjunction with the extension of inflammation from the bladder by continuity, probably explains the condition. An operation would have been certainly fatal, and I was thankful to have escaped the additional risk of death during the use of ether. The urine was so loaded with vesical *débris* that the condition of the kidney could not be accurately determined in advance of the operation.

Exostosis of Humerus. F. R., 12 years old, had an extensive exostosis of the left humerus, at the point of insertion of the pectoralis major and growing quite rapidly. It was entirely removed through an incision parallel with the bone, bone forceps and a chisel being employed. He recovered promptly.

Psoas Abscess. F. S., 48 years old, was admitted April 20, with the following history. He had never been seriously ill until 1884, when he had an attack of malarial fever which confined him to a hospital for seven weeks. About a year ago he noticed a slight pain on the left side of the pelvis, and about the sacro-iliac juncture. This gradually increased, so that he was unable to perform his work. Last August he first noticed a swelling in the upper portion of Scarpa's triangle. This markedly increased until, when he came to the hospital, it occupied almost that entire region. The swelling was soft, fluctuating, and without *bruit;* there was a slight apparent pulsation, but it was not centrifugal and was merely the upheaval of the mass produced by the femoral artery lying beneath it. As the man was totally disabled and was rapidly losing strength and flesh I evacuated the abscess with full Listerian precautions. It contained an enormous quantity of pus, between one and two gallons, and continued for a short time to discharge freely. It was dressed daily and contracted rapidly, it being necessary at each dressing to shorten the drainage tube. When I last saw him he seemed almost entirely recovered.

Rupture of Bladder and Urethra. W. B., 38 years old, while coupling cars on the Reading railroad was caught laterally between the bumpers, the pressure being applied about equally on both sides from the trochanters to the crest of the ilium. He was admitted May 7, complaining of great pain over the right horizontal ramus of the pubis, at which point crepitus could be felt distinctly. He had moderate symptoms of shock. On catheterization a small quantity of bloody urine was obtained. The following day the abdomen became somewhat distended, but the urine gradually became clearer and the bladder more tolerant of it, until at the end of the fifth day the patient passed spontaneously from four to six ounces of perfectly clear urine. His temperature being then in the neighborhood of 100° and his belly flat and painless, I hoped that the source of the blood had been an unimportant rupture of the urethra. Catheterization was stopped and the patient kept on general supporting treatment. He however gradually developed septic symptoms, and two or three days later, upon the appearance of œdema of the lower portion of the abdomen and the upper part of the thighs, I dissected down and opened the cavity of the pelvis just above the ramus of the pubis, finding it filled with pus and with rapidly disintegrating sloughs of the subperitoneal connective tissue. Drainage and irrigation were employed, but without avail; the man died on the 17th, ten days after the

injury. The autopsy showed a rent in the bladder wall, and another not very extensive one in the membranous urethra. That in the bladder showed an attempt at union of the edges, and it would seem possible that some such union by adhesive inflammation took place early in the case, at about the time the blood disappeared from the urine and the bladder became retentive. Undoubtedly, however, some pelvic extravasation had occurred before this time, but the absence of any general or local phenomena pointing to it was truly remarkable. A continuance of the abdominal distention, high temperature and scanty urine would have led to an exploratory operation; but the subsidence of all these symptoms seemed to make an operation unjustifiable, although it was carefully discussed.

Lymphadenoma With a History of Hernia. B. S., 61 years old, was admitted with the history of the sudden appearance of a tumor just below the line of her left groin, and accompanied with local pain, constipation, vomiting and mild shock. The tumor, she insisted, was precisely similar to one from which she had suffered some years before, and which, she said, the doctor who attended her had caused to disappear by handling. In this history she persisted in spite of careful cross-questioning. The tumor was about half the size of the fist, situated over the saphenous opening, tense and apparently exquisitely tender, so that she could not bear to have it palpated. It was dull on percussion and had no impulse on coughing. She was etherized, when it was found that the tumor was distinctly lobulated. A diagnosis of lymphadenoma was made, though it was thought possible, in view of the history, that there might be a small femoral hernia strangulated in the canal. The growth was cut down upon and removed, but I found there was no trace of a hernial protrusion of any sort. The case is interesting on account of the conflict between the history and the actual condition.

Hemorrhoids. In a case of extensive hemorrhoids in a woman 60 years old, the old operation of ligation was performed. The tumors were left protruding and were dusted daily with iodoform, which is, in my opinion, *the* antiseptic for all operations about the anus. The patient was entirely well in less than two weeks, in spite of her age and of the extensive size of the piles. There was no fever and no development of unpleasant odor after the operation.

Epithelioma. In a case of extensive epithelioma of the lower lip a large portion of the lip and of the soft tissues from the front of the chin was removed. It was found that there was in addition considerable disease of the alveolar process of the inferior maxilla, and I therefore, at the same time, extracted the right lateral incisors, the canines, and the bicuspids, and removed one-half the lower jaw, leaving its lower edge to preserve the contour. There was almost no fever, except for a few hours when a slight erysipelatous blush, the result of tension, made its appearance. The patient was discharged cured in about two weeks.

In addition to these cases, most of which were operative, I may summarize briefly the history of others which came under my care during the three months term of service, many of which were no less interesting. There were ten cases of compound fracture of various bones; in eight of these the highest temperature reached was 100°. In the other two there were other injuries, extensive contusions and subsequent cellulitis, which ran the temperature up for a few days. They all recovered, and all with useful limbs. Of other fractures I may note that in eleven cases of fracture of one or both bones of the leg the average time of stay in the hospital was not more than five weeks. The remaining fractures were simple ones, and included six of the femur, several of the ribs, two of the pelvis (one of which recovered), and numbers of the arm, forearm, and other bones. There were twelve cases of burns and scalds, some of them very extensive. All recovered except one, a woman 60 years old, who died of delirium tremens. Of miscellaneous and unclassifiable cases—contusions, luxations, lacerated wounds, minor abscesses, ulcers, idiopathic erysipelas, urethral stricture, and inflammation, carbuncle, chilblains, necroses, cystitis, sprains, syphilis—there were in the neighborhood of 60 cases, which were worthy of record but which can not be condensed or abstracted without too greatly increasing the length of this paper, the chief object of which will be attained if it serves to call attention to the excellent and extensive charitable work which is being done by the President and Board of Managers of the German Hospital.

1810 South Rittenhouse Square.

—Dr. Roland G. Curtin has been elected Attending Physician, and Dr. W. A. Cochrane Superintendent of the Presbyterian Hospital, Philadelphia.

VALUE OF EXTERNAL EXAMINATION IN OBSTETRIC PRACTICE.[1]

BY CHARLES P. NOBLE, M.D.,
PHILADELPHIA.

The subject of external examination in obstetrics is not so fully appreciated in this country as abroad, especially not when contrasted with France and Austro-Germany. It is not so much the lack of appreciation, in theory, of the importance of external examination which characterizes our country, as the failure to apply in practice this valuable procedure. Being impressed with the utility of external examination as an aid to diagnosis, prognosis and therapeutics in obstetric practice, by my experience and observation in the Philadelphia Lying-in Charity and in private practice, I have chosen this as the subject of the paper I have the honor to read before you to-night.

Abdominal palpation was first described by Mercurius Scipio[2] in 1601, and then by Dionis, Roederer, Smellie and Baudelocque; little importance, however, was attached to it until 1813, when Wigand insisted upon its value and formulated rules for its practice. He failed, however, to impress his views upon the profession. After his time, the method was described, among others, by Velpeau and Chailly, and independently discovered by Hubert; but it remained for Matteï, about the year 1855, to demonstrate its value, not only in the diagnosis of pregnancy, but also for the diagnosis of the presentation and position of the fœtus, and for the purpose of performing version by external manipulation. Tarnier, and his pupils Pinard, Chantreuil and Budin, have succeeded in popularizing this method of exploration.

Auscultation is more generally used in obstetric practice than palpation, owing to the less skill that the former requires. The pulsations of the fœtal heart were first discovered by Mayer in 1818. The discovery was accidental—Mayer was listening for sounds supposed to be caused by the fœtal movements.[3] He did not appreciate the full importance of his discovery. In 1821, Lejumeau de Kergaradec, ignorant of Mayer's discovery, accidentally rediscovered the fœtal heart-tones by auscultation, while endeavoring to listen to sounds produced by the liquor amnii. He presented a memoir on the subject to the Paris Academy in 1821. The ideas of this observer, at first opposed, were soon disseminated throughout Europe; and were defended, among others, by Dubois, Velpeau and Jacquemier. In 1839, Depaul applied auscultation to the diagnosis of fœtal presentations and positions, and after that time all obstetricians adopted it.[1]

As a measure of diagnosis during pregnancy, abdominal palpation not only enables us to establish the fact of pregnancy, but also its duration, the presentation and position of the fœtus, the number of fœtuses present, the life or death of the fœtus, and besides, certain complications of pregnancy such as fibroid tumors of the uterus, ovarian tumors, pelvic exostoses, etc.[2] It will be impossible to give more than a partial presentation of this interesting subject. Aside from the value of abdominal palpation to the obstetrician as a method of diagnosis in ordinary cases of pregnancy—in the knowledge which it affords him of the probability of a normal or a difficult labor, and as the only practicable method of improving his *tactus*—it, together with auscultation, is of the greatest importance in those not uncommon cases of pregnancy in supposed virgins, in which the more usual methods of diagnosis by vaginal examination cannot be employed, owing either to the refractoriness of the patient, or to the hesitancy of the physician to propose such an examination without the strongest reasons therefor. Suspected disease of one of the abdominal viscera is a sufficient excuse for proposing an examination of the abdomen.

The diagnosis of pregnancy, when advanced

[1] Arranged from a paper read before the Northern Medical Association, Sept. 26, 1888.

[2] As showing what may positively or probably be determined by abdominal palpation, I quote from my notes on the lectures of Dr. L. E. Neale, Demonstrator of Obstetrics in the University of Maryland. Points to be determined by abdominal palpation before labor:

I. 1. If the woman be pregnant; 2, the month; 3, primipara or multipara; 4, one or more fœtus; 5, if pregnancy be accompanied by any abnormal condition; 6, presence or absence of extra-uterine pregnancy, with or without normal pregnancy; 7, fœtus alive or dead; 8, situation of fœtus (a) presentation, (b) position; 9, mechanical obstacles to delivery; 10, placenta previa.

During labor. II. 1, if labor has begun; 2, if the pains be true or false; 3, if the pains be regular or irregular; 4, the stage of labor.

After labor. III. 1, The size, shape, consistency, mobility and sensibility of the uterus; 2, presence of clots in the uterus; 3, presence of tumors; 4, condition of the uterine adnexa (whether sensitive, inflamed, or not); 5, tympanites.

beyond the fourth month, can usually be determined readily by abdominal palpation. During the early months the most important diagnostic points are: the central position of the tumor; its consistency; and most of all, the fact that at more or less regular intervals the consistency of the tumor alters markedly—instead of being doughy and compressible it becomes hard, and its contour is more readily determined. The observation (the knowledge of which we owe to Braxton Hicks) of the latter phenomenon, which continues throughout pregnancy, practically settles the diagnosis. Pinard,[1] perhaps the greatest authority on obstetric palpation, considers this sign as not positive, but only probable, of pregnancy; but since he only urges two conditions with which it may be confounded—the contractions of a greatly distended bladder, and of a subperitoneal uterine myo-fibroma—these contractions of the uterus may be accepted as practically a positive sign of pregnancy. By the use of the catheter, or in exceptional cases of distended bladder from retro-versio uteri gravidi, of the aspirator, the diagnosis of distended bladder may be positively established. The probability of mistaking a subperitoneal myo-fibroma for a pregnant uterus is so slight as to merit attention only as a remote possibility; certainly, the observation of the rhythmic contractions of the uterus is a more certain sign of pregnancy than ballottement, which is universally admitted as a positive sign. Among other conditions, aside from pregnancy, which have actually given the sensation of ballottement, may be mentioned:[2] a multilocular cystoma of the ovary (Pajot); a small ovarian cyst with a long pedicle; the non-pregnant anteflexed uterus (Cazeaux); the pregnant womb itself, floating in ascitic fluid (Robert Barnes); a wandering kidney; and a calculus resting on the *bas-fond* of the bladder (Cazeaux). Pinard might have urged another condition — which would likely be confounded with normal pregnancy—tubal pregnancy, going on to term without rupture of the tube. Hæmatometra has also been mentioned as a possible source of error in diagnosis.

About the middle of pregnancy, in addition to the signs mentioned, abdominal ballottement can be obtained. Either the whole fœtus, or simply the head can be ballotted. Even before this time the active fœtal movements may be felt, as was first shown by Pajot[1]; and by the aid of auscultation they may be perceived after the third month. This sign, of course, not only establishes the fact of pregnancy but also the life of the fœtus. During the last half of pregnancy the fœtus can be made out, and usually its exact situation, without difficulty.

Auscultation affords great assistance in the diagnosis of pregnancy. The recognition of the uterine souffle was formerly regarded as a positive evidence of pregnancy; but it is now known that similar sounds can at times be heard over uterine fibroids and ovarian tumors. The recognition of the fœtal heart-tones, however, is positive evidence both of pregnancy and of the life of the fœtus. The sounds of the fœtal heart are heard, according to Depaul, after the third month; most authors, however, say after the fourth month. Charpentier[2] states that he has never heard them before the middle of the fourth month, but that after that time he has always found them, provided the fœtus was living. Depaul in 906 cases, examined during the last three months of pregnancy, failed to find the fœtal heart sounds in but 8 cases; and Anderson, of Glasgow, in 180 cases failed to find them in but 12 cases, and in these cases the children were still-born. The theory of Frankenhäuser, that the sex of the fœtus can be determined by the frequency of the cardiac pulsations, has not been generally accepted. According to Hecker and Schroeder, the fœtal souffle is heard in from 14 to 15 per cent. of all cases. The fœtal souffle is a single or double blowing murmer, isochronous with the fœtal heart beats. Its discoverer, Evory Kennedy, regarded it as due to mechanical interference with the circulation in the cord. Various other explanations have been given of its occurrence; it is known to be due at times to disease of the fœtal heart, as hypertrophy of the right ventricle, with insufficiency of the tricuspid and mitral valves, with vegetations on them. Its recognition cannot be considered of much practical moment, nor is this easy. In the course of my investigations I have never observed it. The active fœtal movements can be recognized not only by palpation but also, and much earlier, by auscultation. Pajot in particular has studied this subject. At the end of the third

month a bruit is produced comparable to the sound caused by the tapping of the finger against a tense membrane. This sound is caused by the total displacement of the fœtus. Toward the end of gestation the sound is caused by movements of the extremities. If the stethoscope or ear be applied over the uterus, during active fœtal movements, both the delicate bruit and the sense of shock caused by the impact of the fœtus or its extremities against the uterine wall, can be heard and felt. The recognition of the fœtal movements by the skilled observer is positive evidence of pregnancy and of the life of the fœtus, and is a valuable aid to diagnosis in the fourth month.

The value of palpation in establishing the diagnosis of the presentation and position of the fœtus can scarcely be overestimated. It has been urged that before labor the presentation of the fœtus is a matter of little importance, and that during labor vaginal touch affords all necessary information. This argument is certainly fallacious. It might perhaps be a matter of little importance what part of the fœtus offered at the superior strait during pregnancy, if pregnancy was not to be terminated by labor; and again, if all presentations of the fœtus were normal, and labor equally easy and safe in each of them, it might not matter that the accoucheur possessed no knowledge of the relation between the fœtus and its mother except that obtained by vaginal examination at his first visit after the advent of labor. But these conditions do not hold. It is generally recognized that vaginal examination during pregnancy to discover the presentation and position of the fœtus, and the relation of the diameters and circumference of the presenting part of the fœtus to those of the pelvis, except under unusual conditions, is impracticable. The same is not true of external examination. Besides, more exact and greater information can be obtained during pregnancy by external than by internal examination. Of course neither method of examination is to be employed to the exclusion of the other. The knowledge obtained by each method is complementary to that obtained by the other. Fortunately, however, such complete information is usually obtained by external examination as to render internal examination unnecessary during pregnancy. In a given case, with the presentation and position of the fœtus, and the capacity of the pelvis made out during the eighth or ninth calender month, the obstetrician occupies a very different position from what he would were these facts unknown to him. Should nothing abnormal be discovered he has the assurance that no serious mechanical obstacle to delivery will be encountered during labor. Should abnormality of the fœtus, of its presentation, or of the maternal pelvis be discovered, he is forewarned, and is enabled to institute the proper obstetric treatment at the proper time—whether this be version, the induction of premature labor, or other obstetric procedure.

Auscultation is of special use in diagnosticating the presentations and positions of the fœtus *in utero*, as first pointed out by De Kergaradec. According to Depaul the fœtal heart is so situated as to be nearer the cephalic than the pelvic extremity, and since the attitude of the fœtus is that of anterior flexion, the heart-sounds are most easily transmitted to the ear through the back. The point of maximum intensity will be over the fœtal dorsal region, corresponding to the fœtal pericardium. If the fœtus be presenting by the vertex, this point will be below a horizontal line dividing the uterus in two equal parts: the umbilicus cannot serve as an accurate landmark owing to its variable position. In pelvic presentations, on the other hand, the fœtal heart will be heard with greatest intensity above this line—in the upper part of the uterus. While the conclusions of Depaul are nearly universally admitted,[1] a part of his premises have been shown by Ribemont to be incorrect. This observer has shown by means of frozen sections that the fœtal heart is about equidistant from the poles of the fœtal ovoid; and that the explanation of the fact that the fœtal heart is heard most distinctly below the horizontal line in vertex presentations, is found in the engagement of the head, which occurs before labor in this presentation but in no other. This theory is undoubtedly correct, and amply explains the fact that, in those cases of vertex presentation in which lack of relation between the size of head and the capacity of the pelvis prevent engagement before labor, the fœtal heart-sounds are heard most distinctly at or near the horizontal line. In this way, presentations of the vertex or breech are distinguished. According as the heart is heard most distinctly to the right or left of the linea alba, the position is right or left. Auscultation is of doubtful value in the diagnosis of face

[1] Tarnier and Chantreuil have stated that in cases of placenta previa, deformed pelvis, large fœtal head, or other condition which prevents the head from engaging, the fœtal heart may be heard above the horizontal line.

and shoulder presentations. By combining it with palpation, however, the diagnosis can be made. But since face presentations are rare during labor, and infinitely more rare during pregnancy, the method is of theoretical rather than of practical value in these cases. The same rules apply to the diagnosis of the presentation and positions during labor by auscultation, except that as the presenting part sinks down in the pelvis, the fœtal heart is heard at a correspondingly lower point.

During labor, abdominal palpation affords valuable information, and that, too, without entailing any danger upon the patient. Modern investigation has shown the danger of conveying sepsis to the patient by frequent "touching," unless the strictest antiseptic measures are employed; and even when this is done frequent touching is to be deprecated. I by no means accept the teaching of some, as Credé, that abdominal palpation alone shall be employed during labor, except under peculiar circumstances; but I do believe that vaginal examination is abused at the present time. When the presenting part is "high up," palpation affords much more accurate information than internal examination, which under these circumstances gives notoriously incomplete and unsatisfactory results. It is not my purpose to discuss this question from the medico-legal aspect—a reference to the recent discussions upon this point before the Chicago Gynecological and Medico-Legal Societies being sufficient to indicate the drift of professional opinion at this time. In ordinary labors, then, palpation should be employed because sometimes it yields the same, sometimes greater information than vaginal examination; and in all cases the information gained by touch is supplemented, confirmed, or corrected by that obtained from external examination. In long tedious labors, by inspection and palpation alone can we determine the state of the uterus, and especially its lower segment —important matters in such labors, affording an indication for artificial delivery, or, when this has been neglected, giving a warning of approaching rupture of the uterus.

Auscultation, moreover, should not be neglected during labor, though the information it affords relates rather to the fœtus than the mother. In this way alone can we derive reliable information concerning the condition of the fœtus. Kilian, in 1849, formulated what is sometimes called the "stethoscopical indication for forceps delivery." When the fœtal cardiac pulsations increase in number to 180 per minute, or diminish to 100 or less; and when at the same time they lose their purity of tone; when distinct intermissions occur, or when only one sound can be distinctly heard—the life of the fœtus is seriously threatened, and forceps delivery is indicated. This usually occurs in tedious labors, especially during the second stage, and is brought about by the prolonged compression to which the fœtal head and trunk are subjected. In deciding the question, when to conclude a tedious labor artificially, the condition of the fœtus as well as of the mother should be considered. I have seen the suggestion that the fœtal mortality, in labor, is somewhat increased by the efforts of obstetricians to delay labor during the stage of perineal distention, in order to preserve the integrity of this structure. This suggestion deserves consideration, and the condition of the fœtus, as indicated by the character and frequency of the heart-sounds, should be determined before effort is made to lengthen this period of labor.

Palpation after labor is so generally practiced, and its value as affording accurate information concerning the uterus and adnexa and the abdominal viscera so thoroughly appreciated, that a brief *résumé* of a few of its most important applications must suffice. Immediately after labor, palpation gives information of the tone of the uterus, and the hand resting gently on the abdomen over the uterus readily appreciates any alteration in the consistency of that organ. The practice of allowing the hand to rest gently over the uterus, for some time after labor, cannot be too strongly commended. In no other way can post-partum hemorrhage be so surely prevented; because relaxation of the uterus is immediately appreciated and measures to secure its contraction can be taken at once. Gentle friction of the uterus, during the natural contractions, assists in expelling clots and preventing after-pains.

Daily palpation of the abdomen during the first days of the puerperium should never be neglected. The condition of the uterus and adnexa can thus be known from day to day. The information gained in this way is scarcely less valuable, in indicating the progress of the case, than that afforded by the observation of the pulse and temperature. In a normal puerperal case the uterus during the first three or four days is found in the hypogastrium, well contracted, and not sensitive to pressure. After the third or fourth

day it rapidly diminishes in size, so that at the end of a week or ten days it is scarcely palpable from the abdomen. The adnexa during this time, are not painful on pressure. By daily palpation any deviation from this course is at once discovered. The process of involution is markedly influenced by intercurrent diseases, especially by septic or putrid infection. Indeed, the beginning of septicæmia or putrid infection is indicated by the large, relaxed, sensitive uterus, almost as soon as by the increased bodily heat, or rapidity of the pulse. This is especially true when the uterus is the site of absorption. It should be mentioned, also, that palpation offers the surest means of differentiating between after-pains of spasmodic character—perhaps induced by ergotism—and those caused by a relaxed state of the uterus, which favors passive hemorrhage and the retention of clots. The indications for treatment in the two classes of cases being radically different, a correct differentiation is essential for satisfactory therapeusis.

A practical matter, while not strictly apposite, may be mentioned here. It is the physician's duty to see that the nurse follows his directions, especially with reference to the cleanliness of the patient, her bed, and clothing. A clean bed-spread and some attar of roses, may conceal from the physician, who neglects palpation during the puerperium, a very dangerous condition. Indeed it is well known that lazy nurses in this way endeavor to conceal the results of their negligence. Unclean bedding, or undergarments, or putrid discharges, can scarcely escape the attention of the physician who examines the abdomen as a useful routine practice at his daily visit. By stooping over the patient the nose can be brought sufficiently near the pubes to detect even a slight putrescent odor, and that without attracting the patient's attention or wounding her sensibilities.

Surely, the man who employs all the resources of his art is likely to be the most accurate diagnostician and successful practitioner.

—Professor Osler, whose election to the position of Professor of the Practice of Medicine in Johns Hopkins University was announced in the Reporter, October 13, will not enter upon his duties there until next May. During this winter he will continue to fill the position of Professor of Clinical Medicine at the University of Pennsylvania.

THE INFANT'S PULSE.

BY WILLIAM A. EDWARDS, M.D.,

INSTRUCTOR IN CLINICAL MEDICINE AND PHYSICIAN TO THE MEDICAL DISPENSARY IN THE UNIVERSITY OF PENNSYLVANIA; PHYSICIAN TO ST. JOSEPH'S HOSPITAL AND TO THE DEP'T FOR DISEASES OF CHILDREN; FELLOW OF THE COLLEGE OF PHYSICIANS; ETC., ETC.

Notwithstanding the importance that is attached to the pulse in adult practice, it is somewhat remarkable that its characteristics in early life are almost unrecorded. It is true that Valleix and Trousseau have formulated their observations on the pulse of the healthy infant, but, unfortunately for practical use, these gentlemen do not agree in their statistics. Cardiac pulsations are of clinical importance very early in fœtal life. Mayor, in 1818, was probably the first to put this knowledge to practical service. He was followed by Frankenhäuser who still further investigated the fœtal heart sounds; and very recently, such an authority as Jacobi has stated that he was rarely mistaken in diagnosticating the sex of the fœtus by the character and rhythm of the heart sounds.

In endeavoring to establish a normal standard of the pulse from the moment of birth up to the end of the first year one is met by many difficulties. It is with difficulty that the pulse can be recorded for the first hour after birth; sometimes not until ten days have elapsed can the pulse at the wrist be counted with any degree of accuracy. The first alteration in the pulse after birth is a decrease in its frequency; within an hour it will settle down to an average beat of 136, whereas before birth it has fluctuated between 124 and 150. During the first eighth to quarter-minute after birth the heart pulsations are not discernable; then they commence slowly, so that by the first half-minute they are probably not more than 10 or 12 per minute. At this time a vigorous child will cry, and the pulse rate will become rapidly increased, possibly up to 160, settling down in a short time to between 136 and 140.

Trousseau states that the average pulse of the healthy infant between the first and second month is 137 a minute; from the third to the sixth month 128; and from the sixth to the twelfth month 120.

The infant's pulse is more rapid while it is awake, especially if it is sitting or standing. Muscular or mental emotion may cause the pulse to become extremely rapid; this

rapidity is most marked in feeble children. Sleep reduces the number of pulse beats very materially. As the child grows older the pulse becomes less impressionable; the child at six years presents an average pulse of 100, and at thirteen one of 88.

The most marked characteristic of the infants pulse is *irregularity*, which occurs whether the child is asleep or awake, at rest or in active movement. Conditions which will hardly perceptibly affect the pulse of the adult will derange the rhythm of the infants pulse to a marked degree; disorders of digestion so common in infancy show marked effect upon the pulse rhythm. Irregularity is also seen during constipation or diarrhœa, and is associated with intestinal worms and with dentition. An important and as yet unrecorded difference between the infant's pulse and that of the adult is the fact that in the former there is an entire absence of dicrotism, and it does not appear until the child has reached the tenth to fourteenth year. Space forbids a full discussion of this peculiarity, but suffice it to say that the infant's pulse has not the same recoil as the adult's; it has furthermore been demonstrated that blood-pressure in the young is very low, and that dicrotism in the adult pulse is produced by conditions that do not exist in the infant. It is also well known, since Marey demonstrated the fact, that the longer the vessel, the greater the dicrotism. Infants present great variability in the size of their arteries; in some of the diatheses the blood vessels are much altered; for example, rickets is attended by large arteries. On the other hand the arterial system may be unduly small. I have elsewhere called attention to this congenital smallness of the arteries. The character of the pulse in infants is difficult to describe; it yields readily to the finger of the observer, is small, irregular, and does not present any marked difference between systole and diastole. One observer aptly remarks that the pulse of infants is deprived of sense, rules, or proportion—a description to which I hesitate to add a single word, so liable is the pulse to be affected by most trivial departures from health. Even a slight accumulation of flatus, for instance, will so alter the pulse that, judging from it alone, one could not avoid concluding that the little patient was the subject of a grave disease.

While irregularity in rhythm may be considered one of the normal features of the pulse, it is not so, however, with *persistent frequency* which is always a manifestation of cardiac overstrain, no matter how young the child may be; it also occurs in association with anæmia, leukæmia, and malarial intoxication in babes. The frequent action may be constant or paroxysmal in its appearance.

Occasionally in infants we meet with exactly the opposite condition, namely, *infrequent pulse*, which is usually congenital, although I have several times observed an infrequent pulse associated with the jaundice that is common during the early months of life, and also with renal disorders. The congenital cases are liable to present also evidences of cerebral disturbances, great mental excitement or epileptiform attacks.

Society Reports.

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING, AT WASHINGTON, D. C., SEPTEMBER 18, 19 AND 20, 1888.

Thursday, Third Day, Sept. 20.

MORNING SESSION.

George W. Gay, M.D., Boston, read a paper on

The Comparative Merits of Tracheotomy and Intubation in the Treatment of Croup.

Dr. O'Dwyer's method of intubing the larynx has now been before the profession in a prominent manner about three years, and it is surely gaining favor as its merits and its limitations are being more clearly understood.

The operation has its advantages and its disadvantages. It gives relief to the dyspnœa and it saves lives. The statistics of recovery vary much, as in tracheotomy. Twenty-six per cent. is a fair average after intubation. The recovery rate in 327 tracheotomies performed at the Boston City Hospital, was 29 per cent. In about 100 cases of intubation performed at the same institution the rate of recovery was 26 per cent. showing a little smaller percentage than the old operation. It is not claimed that these figures and facts are conclusive. The number of intubations is, as yet too small to settle the question. The recovery of patients under three years of age was in the same proportion after each operation, namely 12 per cent.

O'Dwyer, Brown and Waxham save about one in four after intubation; Huber and

Montgomery save one in two; Northrup and Denhard save one in five; Jenning, one in ten; Chatham, one in fifteen; and A. B. Strong, one in thirty-one. This variation of results in the experience of different operators, proves conclusively that the type of the disease determines the result to a great extent, far more in fact, than any mode of treatment.

The conclusion on this point is that the new operation saves nearly or quite as many patients as did the old.

In regard to the facility of doing intubation, it may like tracheotomy be easy or difficult, according to the age of the child, the condition of the larynx and the strength of the patient. Both operations are difficult in children under three or four years of age and both are attended with some danger. In tracheotomy the risk lies principally in hemorrhage and collapse. In intubation it lies in pushing membrane, etc., down in front of the tube, producing more or less complete obstruction. In very weak children collapse may result from prolonged efforts at placing the laryngeal tube. Under these circumstances the surgeon should choose the operation with which he is most familiar. The old operation can be done with one good assistant. Intubation requires at least two fairly good ones. Unless great care be taken the operator's fingers may be severely bitten, which in at least one case, has resulted in death.

It is desirable to have a physician close at hand for 3 or 4 days after both operations. If the tube must be allowed to take care of itself intubation is preferable. If ordinary care, such as a good nurse or other clever person can give, is available in cases located at a great distance from a physician who can place O'Dwyer's tubes, then the old operation is better, there being less danger of fatal obstruction and the question of feeding giving less anxiety.

The weight of testimony goes to prove that it is less work to take care of intubated than of tracheotomized patients. The time occupied in caring for the tube in the latter class, is largely taken up in feeding the former class of patients.

Northrup's statistics of 107 autopsies performed at the N. Y. Foundling Hospital go to prove that there is no such thing as "food pneumonia," as in no instance were signs of food found in the smaller bronchi. Dr. O'Dwyer advances the opinion that the secondary lung affections, especially of pneumonia, are due to retained secretions which, owing to the presence of the tube in either operation, cannot be ejected by coughing. Others think that this complication is due to the fact that the air enters the lungs without first being warmed and moistened by passing through the nasal chambers. The author ascribes these affections to the natural tendency of exudative processes to extend in all directions, and bases the opinion upon the fact that pulmonary complications are as frequent in cases not receiving surgical treatment, run the same course and are as fatal as in those in which operation is resorted to.

While a wound in the skin is objectionable on general principles, yet the wound of tracheotomy gives little trouble and does little harm. The diphtheritic poison gains admission to the system before the wound exists and the course of the disease as regards sepsis is the same after as before the operation. In only six of the 327 operations at the City Hospital of Boston was diphtheria in the wound noted; three of these cases recovered. Both tubes may produce ulceration in the trachea, but the result is seldom serious.

Conclusions.—1. Intubation may be tried in all cases of croup.

2. It is preferable in young children and in cases in which the tube must be left entirely to itself.

3. It may be resorted to for euthanasia, provided the operator is reasonably expert and can do it without producing collapse.

4. Tracheotomy is called for in those cases in which intubation can not be done or in which it fails to give relief; or in which the laryngeal tube is repeatedly ejected or requires frequent removal for cleansing. It may also be required in those cases in which sufficient food can not be given while the O'Dwyer tube is in position. It is also preferable in cases situated at a distance from a surgeon capable of introducing the laryngeal tube.

5. The tracheotomy instruments should always be at hand in intubation in case of emergency.

In opening the discussion on the paper of Dr. Gay, Dr. H. H. Mudd, St. Louis, said that intubation had been done as a precautionary measure in many cases, in which tracheotomy would not have been thought of. Some of the good results of intubation are to be attributed to this fact. In most of his cases of intubation where the patient survived he had found it necessary to resort to tracheotomy. Patients have recovered after tracheotomy where intubation has proved unsuccessful.

Prof. Thomas Annandale called atten-

tion to the value of the introduction of a tube through the glottis in cases of operation about the throat where there was risk of suffocation or of hemorrhage into the trachea.

Dr. Huber, of New York, had performed intubation in 94 cases with recovery in 37. He does not operate early. He considers the internal use of bichloride of mercury as of equal importance as the intubation. There is occasionally an advantage in using a small tube with the expectation that it will be coughed out and with it a portion of the membrane, and affording an opportunity for feeding while the tube is out.

Dr. T. F. Prewitt, St. Louis, in one case of diphtheritic paralysis had, in order to avoid passage of fluid into larynx, passed a catheter through the glottis and plugged the larnyx with a sponge. This permitted the fluid to go into the œsophagus without risk of entering the trachea. After feeding, the sponge and tube were removed.

Dr. D. W. Cheever, Boston, advocated the disuse of anæsthetics in cases of tracheotomy provided proper assistants can be secured. The operation is not accompanied with much pain. By avoiding the anæsthetic many of the risks of the operation are avoided.

The next paper, by Dr. L. McLane Tiffany, of Baltimore, was entitled

Pregnancy and Operative Surgery: Their Mutual Relations.

The following conclusions were presented:

Conclusions: 1. Pregnancy is a physiological condition and does not contra-indicate a surgical operation. 2. During pregnancy temporary strain may be exerted on some organ, *e.g.*, kidney, inducing impairment of function. 3. A surgical operation upon a pregnant woman is to be conducted so as to avoid inducing abortion, in itself a serious accident. 4. The main cause of abortion after operation is sepsis. 5. The probability of sepsis after operation is increased if the patient is suffering from disease, either temporary or chronic. 6. Abortion may result from operation—shock perhaps. 7. Hæmorrhage does not seem to induce abortion. 8. Union of fracture may be retarded by pregnancy. 9. Recorded cases show that the unborn child receives no evil impress when the mother is subjected to operation. 10. When a surgical operation upon a pregnant woman is under consideration, the function of all the patient's organs must be carefully investigated and regulated. An operation then conducted antiseptically may be expected to result as though pregnancy were not present.

Dr. J. Ewing Mears, Philadelphia, in opening the discussion, thought that while pregnancy was to be regarded as a physiological process in the native woman, it could not be considered in this light in the society woman. Another important point to be considered was whether the operation required was one of expediency or of necessity. In the latter case the surgeon must do his duty let the result be what it may; but whether or not operations of expediency were to be performed on the pregnant was a question only to be decided by further experience.

Dr. P. S. Conner, Cincinnati, reported a case of subcutaneous operation for anchylosis of the knee in a woman who it was subsequently learned was six weeks pregnant. The operation was followed by severe septic infection, but this did not interfere with the normal course of the pregnancy.

Dr. William Hunt, of Philadelphia, raised the question whether or not in the case of inevitably fatal injury of a pregnant woman, as from burns, it was justifiable to run the risk of sacrificing the mother a few days sooner, when by so doing the life of the child might be saved, or must we wait until the last breath has left the body before making the incision?

Dr. R. B. Bontecou, Troy, reported the case of a rupture of an umbilical hernia in a woman seven months pregnant. The intestines were out four hours. They were then cleaned and replaced. The woman recovered, and a healthy child was born one month later.

Dr. L. McLane Tiffany, of Baltimore, thought that in the case suggested by Dr. Hunt, there could be no question as to the propriety of operation. By so doing, one life may be saved.

Dr. N. P. Dandridge, Cincinnati, read a paper on

Nerve Stretching.

The following conclusions were presented: 1. That nerve stretching should be condemned in all forms of central disease, such as tabes, myelitis, etc. 2. That it offers little prospect of relief in tetanus. 3. That it should be regarded as a reliable method in cases of persistent neuralgia and peripheral paralysis of sensation in the extremities. 4. That stretching the facial is indicated in tic-convulsive. 5. That further trial is justified in reflex epilepsy. 6 That stretching the lingual should be tried in painful affections of the tongue. 7. That resection should always be preferred to stretching in

the spinal accessory and in the branches of the fifth nerve, except the lingual.

AFTERNOON SESSION.

Dr. De Forest Willard, Philadelphia, read a paper on

Nephrectomy.

1. Gun-shot wound of the kidney. 2. Tubercular disease of the kidney.

Case I.—Male, mulatto, æt. 17, was shot July 10, 1887, at such close range as to burn clothing and skin. He was able to walk one-fourth of a mile to the hospital, and the shock was but moderate. Symptoms of internal hemorrhage steadily increased, and when seen by Dr. Willard, four hours after the injury, the signs of collapse were imminent. The ball entered just above the 11th rib, three and one-half inches from the spinous process. There was no wound of exit. Almost pure blood was voided from the bladder and continued to flow freely. The entire left side of the abdomen was dull on percussion, and there was every evidence that there had been an escape of intestinal contents as well as urine and blood into the peritoneal cavity.

Abdominal incision was therefore chosen as best suited to arrest hemorrhage, repair injured organs and remove clots. The bladder was found full of blood, but uninjured. Ureters, the same. The huge hæmatocele was found to be retro-peritoneal, filling all the tissues in the loin and downward into the pelvis. The left kidney was traversed by the ball from the centre of the rim to the infundibulum, and the renal artery and vein cut. Aseptic silk ligatures were applied and the organ removed. The ball had passed behind the peritoneum without injuring other organs and could not be found. No blood or fæces were found in the peritoneal cavity. The sight of the extirpation was thoroughly mopped with sublimate solution, 1–10,000, made with boiling distilled water, and the abdomen irrigated with hot distilled water. The utmost precautions were taken to prevent infection and all the dressings were thoroughly antiseptic. The temperature during the next four days varied from 99.4° to 101.4°. About 20 ounces of slightly albuminous urine were secreted daily. The skin was kept active and no signs of uræmia at any time made their appearance. The patient, however, died of loss of blood, shock and exhaustion eighty-six hours after the injury. At the post-mortem no blood or pus was found in the peritoneal cavity and the adhesions between the serous surfaces were very slight. There was no pus at the sight of the nephrectomy and the hæmatocele was perfectly aseptic. The ball had grazed the 11th rib, passed just below the pleura without entering it, had perforated the diaphragm, left kidney, the renal artery and vein and the sheath of the aorta just at the origin of the renal artery, being found lying directly upon the aorta. The right kidney was healthy.

In his remarks Dr. Willard dwelt upon the advantages of abdominal incision, where the probabilities of other organs having been injured, were so great; as hemorrhage could be arrested, perforations repaired and escaped fluid removed. Drainage through the loin or abdomen was not advisable, provided urine had not escaped into the peritoneal cavity before the operation. The hæmatocele if large and retro-peritoneal could not be thoroughly removed and should therefore be allowed to remain undisturbed. All fluids in the abdominal cavity should be removed.

The three primary nephrectomies for gunshot wound thus far reported have all been done by Philadelphia surgeons. Keen (Trans. Amer. Surg. Asso. vol. v, p. 193) removed the left kidney of a girl of 18, in whom the ball had perforated the stomach, liver, spleen and kidney. This patient died on the 15th day. Price (Trans. Penna. State Society, 1888) removed the right kidney in a girl of 14, in whom the liver was also perforated. His patient recovered after multiple abscess of the liver. Dr. Willard's case died on the fourth day. In none of these cases was there anuria.

Nephrectomy for Tubercular Kidney.

Case II.—Female, æt. 32, married 8 years but never pregnant. Tubercular history of ancestry uncertain. Failing in health for ten months. Seven weeks ago first noticed tumor in right side of abdomen. Has had increasing pain in this region. This is now very severe at times. Has emaciated rapidly. Temperature varying from 99° in the morning to 101° in the evening. Diarrhœa quite constant. Passes large amounts of pus in the urine. Urine 1-6 albuminous but contains no casts and no distinctive cell elements. Tumor rounded in form occupies the space from the right renal region forward to linea semilunaris and vertically from lower margin of liver to line of anterior superior spinous process. Indistinct dullness extending into pelvis. Resonance between liver and tumor. Tumor movable.

Diagnosis uncertain as to purulent kidney or sarcoma of kidney. The size of the tumor and its projection forward determined the selection of the abdominal median incision. The right side of abdomen was found filled with thick sack giving indistinct sense of fluctuation. From it extended downward, two elongated masses, one evidently a pus-filled ureter, and the other a mass extending down from the external iliac vessels and passing under Poupart's ligament. Puncture evacuated only a few drachms of pus and did not diminish its size. Tearing open the sac the kidney was found riddled with multiple abscesses. The vessels and the ureter low down, were tied with silk ligatures and the kidney removed. The abdominal cavity was irrigated with distilled water, drainage tubes inserted behind the uterus and into the site of the nephrectomy, and the wound closed with one set of sutures. The woman was exceedingly low during the operation, but rallied so that the temperature rose to 99° and she became perfectly conscious. Two hours after operation she suddenly sank and died.

The post mortem showed that behind the suppurating kidney and in a separate sack, divided from it by a wall two lines in thickness, was another pus sac. This sac was three inches wide and the pus had worked its way down the aorta, common iliac and iliac arteries to Poupart's ligament. If nephrotomy had been attempted this sack might have been drained and the kidney never reached at all. No hemorrhage after operation. Death from shock. The other kidney was enlarged but not diseased.

In opening the discussion, Dr. W. W. Keen, Philadelphia, said that blood exuded between the folds of the peritoneum was not a source of danger and that it might be left without interference. If we could make out that the kidney alone was injured the lumbar incision would be the proper one. Where there is a probability of injury of other structures, the abdominal incision is the best.

Dr. James McCann, Pittsburg, reported a case of nephrectomy for multiple abscess in which the patient died suddenly six hours after operation.

Dr. L. McLane Tiffany, of Baltimore, held that in simple gunshot wound of the kidney the proper plan was to drain the kidney through the lumbar region and not to perform nephrectomy.

Dr. Chas. T. Parkes, Chicago, reported a case of gunshot injury of the abdomen, in which in addition to a number of perforations in the bowel the ball entered the kidney. The intestinal wounds were closed. No operative procedure was performed on the kidney. The patient died from hemorrhage from the kidney 24 hours later.

Dr. Keen thought that in the condition referred to by Dr. Tiffany, the proper plan was to drain, but where there is much injury of other parts the patient will stand a better chance if the wounded kidney is removed.

Dr. Robert F. Weir, New York: If there is simply a gun-shot wound of the kidney, the organ should be thoroughly exposed in order to ascertain the extent of the injury. Then thorough drainage should be employed and to guard against hemorrhage, the wound should be tamponed with iodoform gauze.

Dr. H. H. Mudd, St. Louis, reported a case of lacerated wound of the kidney in which drainage was adopted. Irregular fever and loss of strength supervened and 51 days after the injury the kidney was removed. The whole organ was in a state of parenchymatous nephritis.

Dr. C. B. Nancrede, Philadelphia, had in his paper last year recommended that in gun-shot wounds of the abdomen involving the kidney, an attempt should be made to save the organ when that was possible. He had also suggested packing of the kidney to prevent hemorrhage.

Dr. R. N. Isham, of Chicago, considered hæmaturia a pathognomonic sign of injury of the kidney. There are two forms of laceration of the kidney, those in which the capsule is involved in the injury and those in which it is not. In the first operation will probably be required. In the second no operative procedure may be required.

Dr. David W. Cheever, Boston read a paper on

Shock.

The operative surgery of our time has annulled pain, arrested hemorrhage, averted septic absorption, but it has not prevented shock. The object of the paper was to inquire whether or not modern surgical procedure had diminished shock, wherein it fails to do so, and to suggest improvement of its defects. A simple description of the degrees of shock is: apprehension, fluttering, sweating, chilliness, pain, vertigo, nausea, faintness, convulsions, unconsciousness and collapse. Moderate shock terminates in reaction. Severe shock is more lasting and is a condition where a feather turns the scale against the patient. An operation at this period causes renewed and prolonged shock. The effect of modern surgery has

been to diminish primary shock and to increase secondary shock. The time of an operation since the introduction of anæsthetics has been much prolonged. Do we realize what this prolonged cutting, pinching and dissection mean to the nervous system? It is unphilosophical and fatal to operate in cases of primary shock before reaction has come on. The golden moment of fairly established reaction must be seized before traumatic fever sets in. This moment comes in from six to eighteen hours after the injury or it never comes. Anæsthesia does not diminish existing shock, but only annuls the additional shock from pain produced by cutting. If prolonged it adds to the secondary shock. There is lowering of bodily temperature after operation under anæsthesia, even to 97° or 96°. This is due to the anæsthesia which, if prolonged, ends in dripping sweat; to careless exposure of patient; largely to antiseptic irrigation, and to the application of cloths wet with antiseptic solutions around seat of injury. Nausea frequently follows anæsthesia. This is one of the marked symptom of severe shock. It is a most dangerous factor in preventing reaction.

In order to diminish shock: 1. wait for reaction. 2. Never neglect to calm the mental state by a cheerful word and personal presence. 3. Give alcohol a quarter of an hour before anæsthetics. 4. Make the anæsthesia short. 5. Operate as rapidly as possible. 6. As short dressing as possible. 7. Avoid chilling of the patient.

To promote reaction after operation: 1. Persistently and carefully applied dry heat. 2. Liquid nourishment combined with a stimulant and a little laudanum by enema. 3. Subcutaneous injection of brandy. 4. Aromatic spirits of ammonia by the mouth. 5. Black coffee and brandy—the stimulant par excellence when it can be retained by the stomach. 6. Quiet; a more than horizontal position; sleep; assurance that all is over and doing well.

Modern surgery has won three great triumphs. 1. It substitutes sleep for pain. 2. It averts secondary hemorrhage by animal ligature. 3. It prevents fermentation by germicidal applications.

4. Can we add a fourth by stilling the nervous system and averting secondary shock?

In opening the discussion, Dr. W. W. Gay, Boston, dwelt upon the importance of preserving animal heat. He is in the habit of using a small dose of morphia hypodermically (1-12 to 1-20) before beginning a capital operation. If the operation is a severe one, the patient is not removed from his bed and is given only a few whiffs of ether to obtund the pain of the first incision.

Dr. C. B. Nancrede, Philadelphia, was in the habit in cases where it was doubtful whether or not the patient had recovered sufficiently to bear an operation, of employing the "ether test." If after the administration of the anæsthetic is commenced, the pulse and the general condition improves, the patient will stand the shock of the operation. If however, the respirations increase in rapidity and the pulse becomes frequent and weak, the ether is removed. These patients never react. Shock is often kept up by a crushed limb. In these cases the condition often rapidly improves when the limb is removed. In order to favor the flow of blood to the head, and to overcome the consequence of its collection in the abdominal vessels he had employed elevation of the limb and the application of the Esmarch bandage.

Dr. Lange, of New York, thought that the influence of loss of blood in the production of shock, was under-rated. He could not recall an instance of prolonged operation in which shock followed provided extreme loss of blood was prevented. In operations where loss of blood is apprehended, he employs large rectal injections of hot water.

Dr. B. A. Watson, of Jersey City, referred to the experiments which he had made showing the influence of ether and of chloroform on temperature.

Dr. David Prince, of Jacksonville, recommended the use of small doses of morphia with tincture of digitalis hypodermically to guard against reflex action and against depression. He considered reflex action an important cause of shock. He also advised that the temperature of the part operated upon should be maintained.

The paper was also discussed by Drs. Weir, Bontecou, Tiffany, Willard, and Moore. Dr. B. A. Watson, Jersey City, moved that a vote of thanks be extended Dr. C. H. Mastin of Mobile for his efforts in introducing and perfecting the plan of organization of the Congress of American Physicians and Surgeons. This motion seconded by Dr. E. M. Moore, of Rochester, and by Dr. Wm. H. Pancoast, of Philadelphia, was unanimously adopted.

After extending to the retiring officers a vote of thanks the Association adjourned to meet in Washington, the second Tuesday of May, 1889.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, September 26, 1888.

The President, J. Solis-Cohen, M.D., in the chair.

Dr. Samuel W. Gross read the following paper on

The Treatment of Carcinoma of the Breast.

Of operations which do not rank with major procedures, not one is more commonly practised by men not skilled in the manual of surgery than that of the removal of the mammary gland for carcinoma. The superficial situation of the organ, the ease with which hemorrhage is controlled, the flaps are united, and the dressings applied, all tend to make partial or complete extirpation of the breast a tempting field for the young surgeon. If to these considerations be added the great frequency of the disease, it will be seen that its treatment should constitute an instructive topic for consideration and discussion by this body.

In accepting your invitation, Mr. President, to make the opening remarks upon the subject, I take it that a brief narration of my own personal experience will prove to be more interesting than were I to deal with the practice of others, the more especially as the operation which I have performed is more thorough than the usual procedure.

At the outset I will state that in the management of so lethal an affection I have relied upon the scalpel, as I believe it to be the one and only measure which is capable of affording good results. It may be that some of my hearers are sceptical as to the propriety of interference. The old tradition that carcinoma is an outward evidence of a blood disorder, and that it cannot, consequently, be cured by operation, may still influence a few of our members. To these I may be permitted to say, first, that the leading minds of the world now admit that carcinoma is primarily a local growth; and, secondly, as I have elsewhere[1] conclusively shown, from an impartial examination of a large number of cases, that the knife not only prevents the local dissemination of the disease, its extension to the lymphatic glands, and the occurrence of secondary growths in a large percentage of cases, but that it moreover prolongs life, and definitely cures one patient out of every eight and a half.

An operation in a suitable case having been decided upon, the one selected by the majority of surgeons is that with which we are all so familiar, namely, the inclusion of the nipple and a portion of the skin in two elliptical incisions, the reflection of the flaps, and the dissection of the gland from the surrounding tissues. Other surgeons, actuated by the desire to save as much of the gland as possible, limit their efforts to the extirpation of the tumor alone. The first of these procedures is faulty enough; the latter cannot be condemned in too severe terms; and yet, in his recent monograph on "The Operative Surgery of Malignant Disease," Butlin, I am sorry to say, recommends it. A knowledge of the changes which, starting from the tumor itself, ensue in the remainder of the breast, in the adjacent soft tissues, and in the associated lymphatic glands, which changes indicate the local extension of the disease along the lymph paths, ought surely to lead the surgeon to reject such irrational operations. In very exceptional instances a cure may be effected; but we all know what is the common result—a more or less rapid recurrence of the disease; a favorable issue being so uncommon after these incomplete operations that few, if any, of us have ever witnessed it.

Dissatisfaction with my own earlier results and those which I was enabled to follow in the practice of other surgeons led me, ten years ago, to adopt a radical procedure, the object being to effect riddance of all the tissues in which the experience of hundreds of years demonstrates that recurrence, or a new outbreak of the disease, takes place. Hence, in my operation, which is minutely described in the *American Journal of the Medical Sciences* for April, 1888, I amputate, by a circular cut, the entire breast with its overlying skin and fat, dissect off the pectoral fascia, and carry an incision into the axilla, through which I am enabled to extirpate its contents. If nodules should be found in the pectoral or intercostal muscles, they are also removed with an equally unsparing hand. The edges of the wounds are then approximated, the closure of the breast incision being greatly facilitated by raising the flaps from the subjacent tissues for an inch and a half to two inches, and the employment of button sutures. In some cases, the wound cannot be entirely united, so that it has to heal by the process of granulation.

[1] American Journal of the Medical Sciences for April, 1888.

In the discussion which will follow the reading of my paper, I will doubtless be asked, first, Why do you remove the entire breast and its surrounding tissues? and, secondly, Why do you attack the axilla in all cases? My answer is simply because recurrence, or a new outbreak of the disease, ensues in tissues which are left behind in the less radical modes of operating. The accumulated observations of surgeons show that recurrence may be anticipated in the skin and subcutaneous tissues, especially at or near the cicatrice; in the fascia covering the pectoral muscle; in the remnant of the breast from which the tumor alone was excised; in outlying lobules which were overlooked during the performance of the less complete operations, and in the lymphatic glands, especially those of the axilla.

Answering these questions more fully, I would say that sound pathology, as well as experience, demands that the entire mammary gland along with its circumjacent tissues should be amputated; first, because we have to deal with a carcinomatous degeneration commencing at one point, from which the cells migrate in various directions into the remainder of the breast and the surrounding tissues, the extent of which migration into the lymphatics and their radicles it is impossible to determine with the naked eye; secondly, because the disease is sometimes multiple, and the smaller growths are only detected on examining the breast after its removal; thirdly, because minute lobules frequently lie at some distance from the main body of the gland, especially toward the axilla and the clavicle, which may subsequently become the seat of a new outbreak, even as late as ten years, as in a remarkable instance recorded by Banks; and, fourthly, because nodules may be found in the subcutaneous tissues at a relatively great distance from the breast, which would certainly have escaped detection in the lesser operations.

My answer to the second question, Why do you attack the axilla in every case? is because the axillary glands are almost always diseased, even though they cannot be felt prior to operation. Of my 45 cases, the glands were not palpable in 18, but in 15 of these they were present when the axillary space was opened. In 57 out of 65 similar cases, Kuester found that the glands were infected, so that our combined experience demonstrates that the glands are invaded in 86 out of every 100 cases in which there is no external evidence of their implication. Hence, if the axilla is not evacuated of its contents in every case, a subsequent operation will almost surely be demanded. In point of fact, I consider this step as the keynote of the procedure, and I refuse to operate if I am not permitted to have my own way in this regard.

Although the procedure which I have described may appear to be unnecessarily severe as to the sacrifice of tissue, and, at first sight, seem to be attended with more risk than operations performed with a more sparing hand, I have still to present some facts which conclusively show that it is the best that has as yet been practised as regards mortality, freedom from local recurrence, and a final cure.

Of my 45 cases, 2, or 4.44 per cent., perished from the operation, and 5 patients were lost sight of after recovery. Deducting the 7 that died and could not be traced, 38 cases show local recurrence in 11, or 28.95 per cent. Including the deaths, out of 40 cases, 9, or 22.5 per cent., recovered. Of these, 1 died of an intercurrent disease in 7 years and 10 months, while the remainder are still doing well: 1 for 9 years and 10 months; 1 for 9 years and 1 month; 1 for 6 years and 9 months; 1 for 4 years and 3 months; 1 for 3 years and 11 months; 2 for 3 years and 6 months; and 1 for 3 years and 5 days.

Let us contrast these results with those afforded by the next best operation, namely, the removal of the breast by flaps and the evacuation of the contents of the axilla in every case. Of 328 cases of this description in the hands of Banks, Kuester, and von Bergmann, 10.67 per cent. perished, there was local recurrence in 54.92 per cent., and 15.15 per cent. were cured; so that my operation is safer by 6.23 per cent., is less liable to local recurrence by 25.97 per cent., and affords 7.35 per cent. more of permanent recoveries.

It is quite certain that the greater immunity from local reproduction of the disease in my operation is due to the total amputation of the breast, its skin, and enveloping fat. Despite the fact that my results are better than any that have heretofore been recorded, a careful examination of the cases of Banks shows that he met with only 3.88 per cent. more of recurrences than I have, and that his percentage of recoveries, namely, 20.77, is only 1.73 per cent. less than my own. Hence, I felt that I might possibly have sacrificed too much of the skin; and, since June, 1887, I have so far modified my operation in 10 cases, the skin

in none being apparently affected, as to save enough of that structure to admit of nice approximation of the edges of the wound. All recovered from the operation; one died from recurrence in the axilla and metastasis; one is living with axillary reproduction; in not one has there been local reproduction; one patient is free from disease at the end of fifteen months; one for one year; one for nine months; and the remainder for periods varying between three and eight months. These cases can be followed and whenever I am sure of being able to trace my patients, I shall give this procedure a fair trial. When, on the other hand, the patient lives at a great distance, or her circumstances are such as to prevent her visiting me in the event of recurrence, I will adhere to the more extensive operation.

Dr. James Collins, in opening the discussion, said: I have on two or three occasions, in the case of small tumors in comparatively young women, allowed myself to be overruled by the patient and her friends, who urged that it would be a pity to sacrifice so much of the breast as I proposed, to performing a restricted operation; but I have regretted it in every instance, and I can assure Prof. Gross that I will never offend again. That which Dr. Gross describes as the "second-best operation," the large elliptical incision with thorough removal of tissues beneath the skin and exploration of the axilla, is the one I have practiced in the majority of my cases. The prolongation of life in those I have been able to follow would average not quite three years.

The great difficulty we have to contend with in mammary tumors is to secure consent to an early operation. Patients go from surgeon to surgeon, and from city to city, and finally consent to an operation as a last resort or in deference to an authoritative opinion; usually, however, too late to escape recurrence. The recurrence which then takes place, despite skillful operation by a distinguished hand, will be cited in discouragement of timely operation in other cases, by a large circle of relatives and friends.

The exploration of the axilla, which the lecturer in his masterly demonstration has so justly emphasized, should never be omitted. Nor is it too trite a remark to recall that antiseptic methods, which have so improved the results of extended operations, should here also remove any lingering dread of opening up large spaces; for they have improved the outlook of the procedure by assisting the rapidity of healing, and excluding the danger of septic accidents and sequelæ.

Dr. O. H. Allis: I have nothing to add in discussion; I have repeatedly seen Prof. Gross operate, and there is one point in his method of operation to which I would call especial attention. The breast having been covered for twenty-four hours with antiseptic solutions and his hands being thoroughly aseptic, he carefully palpates the pectoral region for outlying nodules, marking the site of any that he finds with a pencil-stroke; and when he operates he does not dissect out these places but includes them well within the sweep of the line of incision. In other words, he cuts beyond the outer limits of the disease.

Dr. John B. Roberts: Dr. Gross has for many years taught us all the proper way to remove a breast, that is, to remove it thoroughly. In my own operations, I have, whenever possible, employed the large elliptical incision; the advantage, and I confess the only one, being that when approximation of the edges of the wound is at all possible, it can by this method be more readily effected. No one who has learned from Prof. Gross the proper way to open the axilla would dare to neglect this portion of the operation. As to aseptic and antiseptic methods, there can be no difference of opinion among experienced operators; they are the only methods permissible in operative surgery. I would like to ask Dr. Gross how long it takes to repair one of the large spaces in what he calls the dinner-plate incision, and what his opinion would be as to the prospects of a plastic operation to aid in hastening healing.

Dr. R. Bruce Burns: Of all surgical cases these are the most unsatisfactory. In my earliest operations I did not open the axilla. Three cases operated on in this way are living for eleven, nine, and five years respectively. Of later years I have opened the axilla, and have been unfortunate. Recurrence has taken place in the cicatrices and even in the axillary tissues, perhaps in small glands not removed. I have thought, perhaps, it recurred in the adipose tissues. I have usually employed the elliptical incision. The method of leaving a large open wound to heal by granulation is rather hazardous. In all cases where I have had to depend upon extensive granulation there has been rapid recurrence and metastasis. There may also be limitation of the movements of the arm from matting of the tissues. It is wise always to attempt to secure union by first intention. It would be well

to attempt to remove outlying nodules in the surrounding tissues. Where nodules occupy a portion of the gland (mammary) and are intimately attached to it, the whole organ should be removed.

Antiseptic measures are only so far useful as, in arranging them, you secure aseptic conditions. I believe thorough cleanliness in all respects, as to instruments, dressings, and the surgeon's hands, with good drainage, is all that is necessary in the treatment of the wounds of operations.

Dr. Gross, in closing the discussion, said: There are many points which might have been touched upon in the paper which I omitted for the sake of brevity. Societies do not like to listen to long papers, and the best speakers teach little in long papers. The points I have tried to emphasize are, the importance of a thorough operation, and the fact that its results are better than those of incomplete operations.

Now as to primary union. Of course, I want to get primary union whenever I can. Those who have never seen my operation would be surprised to see how close an approximation we can get by sliding the bistoury under the skin, say for from one to two inches, and then drawing the loosened flaps together with button sutures. Sometimes when there has been very extensive disease, necessitating correspondingly extensive operation, we have a gap left to granulate of two or three fingers' breadth—never more than three fingers' breadth. Healing may be slow in a debilitated subject with a large wound, but averages about six weeks.

Now as to saving the breast, and only removing the tumor itself—I do not care for the breast. It is of no use. I am concerned in getting rid of all diseased tissues. What surgeon would undertake to remove a sarcoma of the thigh, for example, and for the sake of leaving a little more stump, make his flaps through infiltrated tissue? I should consider such a procedure criminal. Yet it is just what some surgeons want us to do in the breast. In my last ten cases I did, for reasons stated in the paper, the lesser operation; and if I find it equally satisfactory in the end, I will adopt it altogether. I am not wedded to one operation, only so far as not only personal experience but the combined statistics of several operators with good results show that my operation has given the best results.

Dr. Burns has had an experience of coincidences. In the cases in which he did not open the axilla and recovery took place, he had a free axilla. I judge that the doctor thinks recurrence takes place in granulations. Now it is a histological fact that granulation tissue will give rise to granulation tissue alone, and not to epithelial tissue. The granulating surface may be great or small; that has nothing at all to do with recurrence. In those other cases all the disease was not removed, and hence development again took place in the tissues forming the bond of union, or the tissues near the cicatrice.

As to aseptic surgery, I can only say that if anyone has been taught the modern methods and neglects them, and death occurs from erysipelas, pyæmia or septic complication, he cannot be held irresponsible.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 4, 1888.

The President, A. Jacobi, M.D., in the chair.

Report of the Delegate to the Congress for the Study of Tuberculosis.

Dr. R. C. M. Page made the report, which had received the verbal approval of Villemin and Landouzy. They had found that true tubercle generally contains the bacillus, which was first supposed to exist by Bouchard, and afterward discovered by Koch. All other substances occurring in non-tuberculous subjects do not contain this bacillus. The bacillus remains virulent in running water at a temperature of 60° F. for six weeks, and in dried sputa for months. It is the cause, not the result of tuberculosis. The disease is contagious under certain conditions, especially in conditions that tend to produce lowered vitality. It is transmitted through cow's milk, beef, etc. In the diagnosis of pulmonary tuberculosis in doubtful cases, the bacillus should be sought for; but it may not be found in the early stage before it has become liberated. As a further test, a lower animal may be inoculated with some of the patient's sputa, and the bacillus be sought for subsequently. No practical means for destroying the bacillus in patients has yet been discovered. Treatment at present is prophylactic—by attention to climate, food, and exercise, and by medicines directed against symptoms as they arise.

The report of the delegate to the British Medical Association was also read.

Dr. E. G. Janeway then read a paper on the

Diagnosis of Diseases of the Liver, and the Fever Accompanying Biliary Obstruction.

Physical examination alone, he said, can not be relied upon in diagnosis of diseases of the liver; the etiology and symptomatology have to be taken into account, and in many cases light will be reflected from the condition of the spleen. It is very easy to make a mistake in estimating the size of the liver. Some, he said, regard tympanitic percussion sound intruding on the space for liver flatness as an absolute sign of perforation of the bowel; but he himself had found this to be due in some cases to the existence of a portion of intestine between the liver and diaphragm, and in others to the liver being turned up by a tumified condition of the abdomen. Adhesion of the liver to the diaphragm from perihepatitis may also prevent tympanitic percussion sound from replacing liver flatness in intestinal perforation. We must take into consideration, he said, in studying diseases of the liver, the condition of the heart, lungs, abdominal viscera, and especially of the kidney. An enlarged right kidney may, in one instance, make the liver appear too small, and in another too large, according as it displaces the liver forward and downward or upward and backward. Aneurism and tumors behind the liver have been known to push the organ forward, making it appear large. The intestine or omentum may become adherent to the liver and make it appear enlarged.

Livers were classified according to size in different diseases, but he mentioned cases in which, in the same disease, the liver was in one instance small and in others large, including, of course, cases of cirrhosis. Dr. Janeway regarded nodulation as an important aid in diagnosis in cancer and cirrhosis; but the liver sometimes appears large and smooth because of distribution. He divided livers up into smooth large livers and large nodular livers, and said that here one must rely on other than physical signs in determining the disease present. Illustrations were given in cirrhosis, waxy liver, and infiltrating cancer. He then took up small livers, and said that moderate diminution in size is often difficult to determine.

Aid in diagnosis, he said, is obtained from jaundice; but here also there is liability to error; for a diseased process surrounding the ducts is more likely to cause jaundice. A limited process may cause it, if it is favorably situated, although jaundice may not be present in a large process. Jaundice is frequently absent in solitary abscess and present in multiple abscess. A case was cited showing that obstruction of the bile-duct is not absolutely necessary to cause complete absence of bile from the feces.

Dr. Janeway then took up

Fever and Jaundice.

Fever, he said, is sometimes present in cancer of the liver, showing that inflammatory process is not absolutely necessary for the production of fever. The fever may be due to an intercurrent process. We were liable, he said, to be deceived by Weil's disease, the nature of which is not yet thoroughly understood. The intermittent hepatic fever of Charcot, which occurs in connection with obstruction of the bile-ducts, may be mistaken for malarial fever. Exploratory puncture has not done harm, but is not sure to reveal abscess when it is present. It should be made deep and in the axillary region, or behind into the right lobe. Perihepatic friction is an aid in pointing to the proper place in which to make puncture.

Dr. A. L. Loomis, replying to a question by the President, said he had not known fever to be absent in multiple abscess, but it is frequently absent in single abscess of the liver; further, in his experience, single abscess of the left lobe is very rare. In this last remark the President agreed, whereas Dr. Janeway had found solitary abscess to be situated in the left lobe as compared with the right lobe in about one-third or one-fourth of the cases. The President said that some observers held that the liver was enlarged in rachitic children, while others denied this. A liability to mistake consists in the fact that the liver in young people is normally large; further, that in rachitics the arteries are large as compared with the heart, and the blood pressure low, and consequently the liver would appear large from mechanical stasis. Again, the deformity of the chest pushes the liver downward and forward, making it appear large. He asked if hematemesis early in cirrhosis might be followed by appreciable diminution in the size of the liver, which early in the disease is large.

Dr. Loomis thought he had seen this result.

Special Correspondence.

LETTER FROM AUSTRALIA.

Melbourne, Sept. 1, 1888.

Sanitary Condition of Melbourne.

The rush and excitement connected with the early days of the great Centennial International Exhibition having subsided, I can now devote some time to jotting down the medical notes taken here and there since my arrival. Melbourne is an active handsome city, with a certain American air. It has broad well-paved streets, with no cobble-stones, so that the drive-way is one broad sheet of lovely smoothness. It is a luxury to ride here. What a comfort to the driving doctor! What a comfort to sick rooms next to streets! Melbourne on its surface is fair as a rose; it blooms with delight. But the comparison stops here; for its odor is worse than all the stinks of Cologne. The stench is that of a rotton, polluted, undrained city—a city teeming with four hundred thousand people, and not a drain, save one in Collons Street and one in Bourke Street. These have been recently laid, and are only for surface water. So-called earth closets are used; but as nine-tenths of them have no earth supplied to them, the sewage system is practically a mere pan receptacle, and is emptied only once a week. It requires a cigar, perfumery, and curses upon such a system to make one's morning visitation to the closet endurable. The people are being taught the danger of this system by the efforts of the Melbourne Health Society; by the visitations of epidemics of typhoid fever; by the fearful death rate among children, high consumption mortality, and by the general high death rate. Now I do not write this in the spirit of captious criticism; it is not hastily spoken. I refer to the reports of the medical men themselves, and among the latter to the Health Officer of the city.

The general death rate of the colony of Victoria is 13.24 per 1000; that of Melbourne 23 per 1000. Consumption gives the high rate of 23.81 for every 10,000 persons living in Melbourne; while Victoria's rate is only 8.91 in the same number of inhabitants. This cannot be explained by the number of deaths in hospitals, nor by the aggregation of population, for the city has a large area, and is not densely populated as compared with the cities of the Old World; nor by unhealthy occupations, as the laboring classes are in a good general condition. They get good wages with short hours, the eight-hour system being in vogue. I think the statements of the Health Officer cover the point, and enforce the lesson now so well known by the medical fraternity—the relation of dampness to consumption and of filth to all zymotic diseases. He says: "In this large and growing city we are yet very much in the condition, as regards drainage facilities, in which we were placed by nature—perhaps a little worse. We have gone on, year after year, saturating the soil with all sorts of stinking abominations, and keeping it constantly soaked with the water from our Yanyean reservoir, and it is impossible that we should not suffer from the damp and foulness so engendered." He is quite sure that the excessive death rate from consumption is owing to the bad drainage. He further states that water pumped from cellars is found to be the rankest compound of the villainous smell that ever offended the nostril; and moreover, this bilge water or sewage is so foul that its contact would pollute the purer water in the gutters, so the law insists that it must be deodorized before it can be pumped out from the cellars into the streets. Melbourne can furnish a warning text for sanitary lecturers. Typhoid fever has been very prevalent here for two years, and sanitarians are directing attention to the need for sanitary improvements. It is unfortunate that the first city of Australia should not lead in these matters; but visitors to Adelaide have been struck with the great improvement effected by the adoption there of a system of deep drainage with utilization of the sewage for agricultural purposes. Not only is there comfort from the increased cleanliness and freedom from smells, but the death rate has been considerably lowered and the citizens appear to be unanimous in opinion that the money required has been well spent. It is the feeling of the Victorian doctors that if the bill for establishing a metropolitan board of works can be carried through Parliament this year, a beginning will be made without delay in the works of drainage.

Australian Health Society.

The Australian Health Society has been in existence twelve years. The objects of the Society are: (1) to create and educate public opinion with regard to sanitary matters in general, by the aid of the platform, the press, and other suitable means; (2) to induce and assist people, by personal influence, example and encouragement to live

in accordance with recognized laws, whereby health is maintained and disease prevented; (3) to seek the removal of all noxious influences deleterious to the public health, and to influence and facilitate legislation in that direction. It is sustained by members who pay five shillings a year. An interesting feature is the meetings for wives and daughters. A series of lectures are given by women, the topics being in the usual orthodox line—circulation and respiration; digestion; the skin; cleanliness; nursing the sick; cooking; dress; accidents, etc. The Society has a large and well patronized library, free to the members of the Society.

I have spoken of the filth question of this city. I find there is a great hue and cry just now of dirt in another direction—the frightful condition of the abattoirs. The accounts published of these are sickening reading. The authorities are at last rousing themselves; a Royal Sanitary Commission has been appointed to enquire into the sanitary condition of the city and its many suburbs; it held its first meeting a few days ago. During the progress of the meeting a Mr. Service, who has been much abroad and looked into these matters, was called upon to "give in his experience." According to this man, the best abattoirs are found in Germany, the worst in Chicago. He said that in Berlin and Munich the abattoirs are kept so clean and tidy that any person could sleep on the premises without experiencing any discomfort. The yards are all carefully paved in order to prevent the retention of any offensive matter, and the method of drainage is perfection. In Berlin they go so far as to practice the æsthetic by the growth of flowering creepers against the wall. He caused much laughter over his description of the Chicago "pork mill." He said that while in the United States, he accompanied a party of men and women on a visit to large abattoirs and a manufacturing establishment in Chicago. It was utterly impossible to approach the yards on foot, the approaches being of the most filthy character, and the yards were in the most unsatisfactory condition; it was one of those institutions in which a pig went in alive at one end and came out tinned pork at the other. Such was the condition of things about the establishment that the women in the party said they would not eat tinned meat again. The question was asked him how they treated the blood at the German abattoirs. This he did not remember, though he saw its importance, as the German sausage is essentially a blood sausage; but he said that after what he had seen at Munich and Berlin he was not afraid to eat anything German. The commission is now taking into consideration the advisability of sending an expert to Germany to critically examine the system in that country.

The comments on the new method of killing criminals by electricity, as sanctioned by the State of New York, have brought out a number of "leaders" in the daily papers of the colonies. The general expression is in favor of the plan. After a very elaborate dissertation upon the subject, the *Argus* says that example does not terrify, and that the gallows conveys no warning to those who live. In fact, it goes so far as to say that the death sentence should not be used too freely; that it can lose its admonishing effect from the very frequency of the spectacle. It concludes that death in the electric chair may be less painful than death on the scaffold, but it means the same for the criminal, and in the absence of any scientific proof to the contrary will continue to mean the same.

New Zealand Doctors.

We are hearing much on all hands just now concerning the great financial depression in New Zealand. At the late Medical Conference held in Auckland, it was found that the doctors are feeling greatly the pinch of the hard times. It was brought out in the meeting that the profession has been affected by a combination of causes; the season has been a healthful one; the people are economizing, and let their trifling ailments go without calling the doctor; then again the old story the world round—there are too many physicians. A rough census taken during the session shows that there are 26 doctors in Dunedin, 22 in Christ Church, 13 in Wellington, 35 in Auckland, besides a number here and there in the country districts. It was the opinion of the Conference that this is too large a proportion of physicians for a healthful climate like New Zealand. How much akin are the tribulations of our profession; some patients can not pay, others will not. How familiar the story sounds that a New Zealand doctor told me: he handed in a bill to a family for twenty-five dollars; he was induced to take fifteen by reason of the stringency of the times. To his disgust, in a few days he learned that the same family had bought a new and expensive piano. The world is wonderfully alike, whether under Ursa Major or under the Southern Cross.

Medical Practitioners Statute.

The medical profession in Australia is regulated by the Medical Practitioners Statute. This authorizes the appointment of a central board of health, which has control of compulsory vaccination; of quarantine; the sanitorium for contagious diseases; the vaccine lymph farm, and all the affairs of sanitation. In justice to this board, after we know what a lamentable condition the drainage is in, it should be said that their powers are greatly hindered by other branches of the government; but a bill is before the House now to increase their powers. The council of each city, town and shire constitutes a local board of health, and all are in close correspondence with the central board. The board annually expends about $75,000, inclusive of about $30,000 in obtaining and keeping up the vaccination of the people. About 85 per cent. of the population are vaccinated, and there are 150 public vaccinators. Rather a unique, but certainly a good power invested in this board, is a supervision of the theatres and places of amusement; the Government refuses the license to such places as are reported unsafe by this body.

The Medical Board consists of three of the medical profession, appointed by the Governor, removable at pleasure. The Board registers the name and addresses of all who are legally qualified to practice. It is proposed to empower the Board, by legislation, to erase from the Register the name of any practitioner guilty of felony or misdemeanor, or for unprofessional conduct. The qualifications for being placed on the Register are: a diploma from any of the colleges of standing in the United Kingdom; of any Colonial college, and any diploma which proves that the holder has passed a regular course of medical study *of not less than three years duration;* the applicant must be native-born or a naturalized citizen. The British Pharmacopœia is the only one recognized. There is also a very stringent Pharmacy law.

The duty of the police medical board is to examine such members of the force as may be sent before it. A strict professional examination is made of each person sent before the board. Upon the Board's report the Police Superannuation Board are guided in their determination whether the applicants are entitled to retire from the force. This makes this body an important one; cases of malingering must be decided, and heavy payments from the public money rest upon its opinion.

There is a medical society in each colony, also an intercolonial one, as well as a branch of the British Medical Association. The Victorian authorities present the curious anomaly of permitting the city at large to be in the most disgraceful condition of filthiness, and yet prosecuting one of its citizens for keeping his premises in an unclean condition. At the Fitzroy court, on Monday last, a butcher was fined forty shillings for keeping on his premises fat and offal in an advanced condition of decomposition; and a dairy man, in the same district, was fined $30 for allowing a manure bin to overflow and for the accumulation of refuse matter at the very door of the place where the milk was laid in pans to "cream." The judge gave him, besides, a stern lecture upon the danger to the community at large of allowing his dairy to fall into such a filthy condition. It is easy to preach, but oh how hard to practice! How any court could have the—well, the brass to fine and lecture an individual in this town is astounding, when the city itself furnishes no example, or in fact any means, for a man to be clean if he so desired.

C. C. Vanderbeck, M.D.

Foreign Correspondence.

LETTER FROM BERLIN.

(from our special correspondent.)

The Royal Charité being the great clinical centre of the German Empire, the yearly publication of the *Charité Annalen* is always looked for with considerable interest in this country. The latest issue, which has just been published, contains so much interesting and valuable information that the readers of the Reporter will no doubt welcome some brief extracts from it. The number of patients treated in the hospital within a year was 19,634; of this number 1893 died, while 14,963 were discharged as either cured or improved. Variola, typhus exanthematicus and recurrent fever did not occur at all; diphtheria, scarlet and typhoid fevers were less frequent, but measles and erysipelas more frequent than in the preceding year. It is a singular fact that delirium tremens was found to be constantly increasing, this increase amounting to not less than 50 per cent. since 1877.

Prof. Leyden, in this volume, discusses four cases pertaining to localization of the cortex cerebri. The first patient, a healthy coachman, was suddenly seized with a right-

sided hemiplegia and total aphasia following over-work, mental excitement and a cold. After convalescence symptoms of a typical Jacksonian epilepsy appeared, simultaneously with right-sided anæsthesia. Death ensued in coma. The autopsy revealed infiltration of the external, and also lesions of the internal capsule. In two other cases there was fracture of the petrous portion of the temporal bone, with left-sided intrameningeal hemorrhage. One patient died, the other recovered. The fourth patient, a syphilitic man, fainted suddenly, and, when he came to, showed aphasia. He was cured, the diagnosis of the case being a gumma of the cortex.

Of more general interest are Professor Fränkel's *bacterioscopic examinations of purulent pleuritic exsudations*, and the diagnostic deductions to which they lead. We reproduce here only the salient points. In a sero-fibrinous pleuritis micro-organisms are not found frequently. If streptococci are present, the formation of empyema is to be looked for, or is already in existence and its pus cells have settled. In empyema, which, of course, can also appear primarily, we find micro-organisms of a most divers nature. Of these, the streptococci and staphylococci are devoid of diagnostic significance. If, however, pneumococci are found exclusively, we have to deal with pleuritis resulting from pneumonia.

Again, if no micro-organisms are found at all, we have to suspect tuberculosis. The tubercular element consists here only in spores, while the tubercle bacilli are but few in number and therefore hard to find.

Professor Brieger communicates a rare *case of tachycardia* with paralysis of the pneumogastric nerve. The patient, a woman 33 years of age, who had borne eleven children, had been a sufferer since her ninth year with dyspnœa and palpitation of the heart. Death resulted from an intercurrent pneumonia. Her pulse registered the enormous number of 250 beats a minute. The diagnosis of paralysis of the pneumogastric nerve was strengthened by the singular fact, that compression of that nerve temporarily aborted the paroxysms.

Professor Fräntzel has contributed an interesting little paper on the *conditions contra-indicating* the *opening of empyemas*. These contra-indications are chiefly the following: 1. When tuberculosis exists simultaneously. 2. When without concomitant phthisis the thorax is rigid and inelastic, and the lung of the affected side remains absolutely inexpansive; as in these cases a perfect healing of the wound cannot be looked for. 3. When we have to deal with an empyema unaccompanied with fever, especially in persons of advanced age. In these cases an operation is more injurious than helpful.

The communications of Professor Bardeleben, the Nestor of German Surgeons (Billroth being an Austrian, Langenbeck no longer living, and Bergmann being a much younger man) invite our attention by the very name of their author. Bardeleben has given special attention to the question of the *most eligible surgical antiseptics*, and is very emphatic in giving iodoform the foremost place. He uses a solution of iodoform in ether and alcohol (one or two parts in eight) for injections and for applications to fistulæ, to carious foci, and for the preparation of iodoform gauze. As a new dressing material, Bardeleben recommends moss paste-board saturated with a 1 to 1000 solution of corrosive sublimate, which is advocated by Hagedorn. The chief advantages of this innovation are cheapness, great absorbent power, and capacity to immobilize a part. Bardeleben's method of preserving cat-gut antiseptically is as follows: The cat-gut is placed for a few days in a five per cent. solution of carbolic acid, then into alcohol, and shortly before being used into a one per cent. solution of corrosive sublimate. For sewing bone Bardeleben uses the aluminium-bronze wire, which was introduced first by Professor Sauer. This substance is both elastic and durable

Of interest also is the report of a death following upon the inhalation of six fluid drachms of chloroform. The patient had a number of lipomata removed, and it is questionable if the anæsthetic caused the result, or if it was an example of one of those sudden deaths in lipomatosis of which Dr. Risch treated in detail some time ago. Throughout the whole of Germany chloroform is the only anæsthetic used, and accidents appear to be of less frequent occurrence with its use than with the use of ether.

Dr. Sommer makes some instructive suggesitons regarding the use of *corrosive sublimate in obstetrical practice*. He believes that the bichloride of mercury is by far the most eligible antiseptic agent for the obstetrician both as regards efficacy and safety. He urges, however, two restrictions to its use, which ought to be borne in mind: viz., not to employ the drug unnecessarily, and to apply it only in great dilution. Sommer advocates dilutions of 1 to 5000 and even of 1 to 8000. Post-partum injections of bichloride into

the uterine cavity should be employed, he says, only: first, after infra-uterine operative interferences; second, after expulsion of macerated fœtal products; third, when there has been fever before parturition; fourth, in atonic hemorrhages. Symptoms of slight and rapidly disappearing poisoning were observed only in four of all the cases treated in a year's time in the Charité. The use of corrosive sublimate during confinement Dr. Sommer restricts to cases with a quick pulse and temperature over 102.2° F; to cases in which there are bad smelling lochia and a sensitive abdomen; and in cases in which there are late hemorrhages.

Professor Brieger has examined pus taken from seven women who died of *puerperal fever*, and found in cultures made from this pus both streptococci and staphylococci, which, transferred to animals, remained wholly inert. He therefore concludes that the fatal issue of the malady does not depend upon these micro-organisms, but upon some other poisonous substances which are generated in the organism. The same author relates the clinical history of a woman which suggests a relation between the hemorrhagic diathesis and pregnancy. The woman in question, 39 years of age, who had borne three children, showed during her fourth confinement hemorrhages from the nose, gums, and lower extremities, hematuria and bloody stools. Shortly after confinement the woman died, without any previous hemorrhages. This, Professor Brieger thinks, appears to point to a possible relation existing between the diathesis and confinement; though regarding the nature of this relation, no definite deductions can as yet be made.

Professor Gerhardt, Dean of the University of Berlin, has enriched the *Charité Annalen* with a study on the *engorgement of the spleen in pneumonia*. He examined twenty-five cases for the above purpose, and found that in seven cases there was no swelling of the spleen; in six the engorgement was noticeable only in the early phases of the affection, while in ten cases the splenic tumefaction lasted throughout the course of the fever. The important point of the study is, of course, Gerhardt's conclusion regarding the pathogenesis of this symptom. He believes that the actual cause of the engorgement of the spleen in pneumonia does not depend upon febrile processes, nor upon micro-organisms, but upon an aggregation of broken down red and white blood-cells in the spleen—a view that is confirmed by certain other appearances in the affection, such as peptonuria and grass-green stools.

Professor Gerhardt furnishes also some interesting notes on a very rare affection—*lightning-stroke*. The patients in question suffered from various forms of nerve irritation. Noticeable were the so-called "lightning figures," *i. e.*, sensations as if electric discharges were continually going on before them. Another singular symptom appearing in this affection was jaundice, caused, in all probability, by the deposit of the coloring matter of the blood in connection with electric influences. Anæsthesia was also noticeable.

Dr. Müller presents two rare cases of *disease of the stomach*—dilatation of the stomach, and hour-glass constriction with alteration of the axis. In both cases there were violent tetanic paroxysms. Tetanus, he says, is one of the most dreaded complications of affections of the stomach, the mortality in such cases being as high as 62.5 per cent. Its etiology has not yet been satisfactorily established. Tetanus in gastric disease has been thought to be due to a desiccation of the tissues, similar to the cramp in the peroneal muscles which occurs in cholera. Another view is that the tetanus is caused by poisoning with ptomaines, generated in the stomach. The author himself regards it as a reflex symptom.

Professor Ehrlich communicates the clinical history of a case of *pernicious anæmia*, in which the pernicious nature of the disease was established during life through examination of the blood. The cause was an injury. The red blood cells were found to be enormously decreased, only numbering 213,000 per cubic millimetre. The leucocytes were reduced in the same proportion, and those formed in bone-marrow were absent altogether. This led to the diagnosis of a grave bone-affection—a view subsequently confirmed by the autopsy, which showed the marrow of the femur to be colorless.

—New cases of yellow fever continue to be reported at Jacksonville, Fla., but are fewer in numbers and not so fatal. The quarantine was raised at Jackson, Mississippi, October 12, and many refugees returned to the city.

—In a paper read before the American Association of Obstetricians and Gynecologists, Sept. 18, 1888 (*American Journal of Obstetrics*, October, 1888), Dr. W. W. Potter reported a case in which he had performed double ovariotomy in a pregnant woman. The patient subsequently went to full term and was delivered of a living child.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

DR. MACKENZIE'S BOOK.

The unfortunate discussions in regard to the treatment of the Crown Prince, and afterward Emperor, Frederick of Germany during his last illness have culminated in the formal presentation by Sir Morell Mackenzie of his side of the controversy. This presentation comes in the shape of a book called: "The Fatal Illness of Frederick the Noble," in which the author endeavors to show that he was altogether right in his management of the case, and those who differed with him were altogether wrong.

It is not strange that Dr. Mackenzie felt the dissent and distrust of his German associates, while his patient lived, or was irritated at their triumph when the diagnosis which they made and he denied was confirmed, and when the false hopes with which he inspired the victim gave place to despair and death. It would not have been improper if he had, in some brief communication to his professional brethren, explained the reasons why he so long and so stoutly maintained that the Crown Prince was not suffering with cancer of the larynx, and refused his assent to the extirpation of the growth. In doing this he might even, without incurring much censure, have answered some of the charges and insinuations against him which he attributed to the envy of German medical men. But, unfortunately for his reputation, he has passed beyond the limits to which a discreet man, conscious of being right and confident of the respect of his professional brethren, would have restricted himself, and has put before the world a statement which will do him more damage than anything which others have stated of him.

We need not now undertake the work of exposing the fatal inconsistencies of Dr. Mackenzie's argument that Gerhardt converted a benign growth in the Crown Prince's larynx into a malignant one, and that Bergmann finally killed him. For our present purpose it is enough to express our condemnation of the spirit which prompted these shameful accusations and our contempt for his undisguised intention to make money out of them.

For the good of our profession, we trust that this book will find no apologists in any civilized land, and that medical men everywhere will do what they can to lessen the disgrace it is likely to bring upon us all by utterly repudiating it. A more stupendous example of the folly to which hatred, malignity, and avarice may drive a man could hardly be imagined; and the responsibility for it may well rest alone upon the individual who was capable of perpetrating it.

THE AIR OF THE BED-ROOM.

The season is now at hand when the problem of ventilation is most important and most difficult of solution. Cold outside, and attempts to maintain a warm temperature inside our houses combine to make living

dangerous to all but the most robust constitutions; and it is not easy to arrange matters so that comfort and safety to health shall go hand in hand. This is especially true in regard to the management of the air in bed-rooms.

There are those who still cling to the idea, which no intelligent medical man now holds, that a cold bed-room is a promoter of health and vigor. Recent studies of the conditions which favor the production of diseases of the lungs leave no doubt that sleeping in a cold room is a most dangerous practice. There are those who can stand it; but it is only because they have unusual powers of resistance. The great mass of mankind, old and young, need to have their bodily temperature carefully maintained at night, and the air they then breathe at about the same temperature as that of the air they breathe by day. Indeed, if there is any difference, it should be that the air which surrounds them when they sleep is somewhat warmer than that in which they move about by day.

For many years those who taught hygiene in popular treatises argued from certain assumptions which had an appearance of soundness, but which were actually unsound, and directly contrary to experience. The fear of what was called foul air led them to underrate the dangers of cold air; and in attempting to escape the former they ran right into the latter. It is strange that these well-meaning teachers failed to see the contradiction to their theories which is furnished by the inhabitants of very cold regions, and that they did not ask themselves why men, and women, and children, who spent the day in the pure and cold air of the Arctic regions and the night in the hot and close atmosphere of their huts, were exceptionally free from diseases of the lungs.

In our day the lesson this fact teaches is better understood, and we know that draughts and a chilly atmosphere in the so-called temperate regions are more dangerous to life and health than foul air seems to be in the frigid zones.

All this is not intended as a defense of foul air; but rather as a warning against cold air. And, those who give advice as physicians may bear it in mind when consulted in regard to the management of living rooms and sleeping rooms in our cold winters. For bed-rooms especially, they may without fear of error recommend a temperature which shall not put any strain upon immature or frail constitutions, and warn their patients against any system of ventilation which involves a cold bed-room.

Bed-rooms should not be over-heated, but they should never be under-heated. A temperature of about 60° is probably a safe one for sleeping apartments. Ventilation should never be secured by means of open windows, but rather by partly opened doors, with precautions to prevent a draught across a bed, or a current of air from a room in which there is any known source of contamination. If a fresher air is desired than many houses have at about the usual hour for retiring, it may be secured by freely ventilating the sleeping-rooms shortly before they are to be occupied, and the rest of the house for a few minutes before the last member of the family goes to bed.

The details of this method can easily be worked out by any intelligent man or woman, and we believe it will furnish a trustworthy means of securing a safe atmosphere as well as a comfortable one.

The matter is so important that we would gladly devote more space to its consideration; but we must leave it here to the consideration of our readers.

TRANSPLANTATION OF SKIN FROM A CORPSE.

In the department for correspondence of this number of the REPORTER will be found a letter on Skin-Grafting, written by that well-known Surgeon, Dr. R. J. Levis. In this letter Dr. Levis expresses his disapproval of the plan of transplanting skin from a corpse

which was described, with favorable comment, in an editorial in the REPORTER, September 22. We have no hesitation in publishing Dr. Levis's criticism of the editorial referred to, because, while we regard honesty of purpose and fair intelligence as essential to the proper discharge of editorial duties, we do not think infallibility is indispensable in an editor. For this reason we shall not fear, if occasion arises, to acknowledge an error or be slow in retracting it. In the present case, it is quite possible that Dr. Levis is right, and that we are wrong; but we cannot see that he has demonstrated the soundness of his position or the error of ours. The only objection he raises, in his letter, against the use of any skin but that of the patient, for skin-grafting, is founded upon a fear which has never, so far as we know, been realized in practice, and which we believe never would be realized if proper precautions were observed in selecting the subject from which the grafts were to be obtained.

In discussing this matter, it must be borne in mind that we speak of exceptional cases. There are very few in which the patient cannot supply the needed grafts. In that of Dr. Bartens, which we referred to in our editorial of September 22, the surgeon may have been wrong in thinking the patient's skin unfit for the purpose. But, if this were the case, it would not affect the general question, and we still believe that, in a case in which skin grafting was necessary, and the grafts could not be obtained from the patient or a healthy donor, it would be good surgery to take them—with precautions similar to those necessary in selecting a living donor—from a corpse.

—Dr. E. Williams, of Cincinnati, Ohio, died in that city recently of an organic disease of the brain, from which he had been a sufferer for about two years.

—Dr. Albert E. Persons has been elected Professor of Materia Medica and Therapeutics in Niagara University, in place of Dr. F. R. Campbell, who recently died.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

A MANUAL FOR HOSPITAL NURSES AND OTHERS ENGAGED IN ATTENDING ON THE SICK. By EDWARD J. DOMVILLE, L.R.C.P., Lond., M.R.C.S., Eng., etc. Sixth edition. Small 8vo, pp. 100. Philadelphia: P. Blakiston, Son & Co., 1888. Price, 75 cents.

This is an admirable little book which might well be in the hands of every nurse, who is such by profession or under the stress of circumstances. Its instructions are perfectly clear and sensible, and with few exceptions are entirely trustworthy. As an exception we note the advice given in regard to the administration of enemata. The author says the tube of the syringe should be passed "through the anus for about four or five inches along the bowel in a direction first backward and then a little forward." In this there are two errors: four or five inches is a greater distance than is necessary; and the tube should be directed first forward, until the sphincter is passed, and then backward along the lower part of the curve of the coccyx and sacrum. We observe also certain Anglicisms in the book, which might need to be translated on this side of the Atlantic; but, on the whole, we have nothing but praise for this excellent manual.

PAMPHLET NOTICES.

[Any reader of the REPORTER who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

THE HISTORY OF ABDOMINAL SECTION IN ALBANY, WITH A REPORT OF SEVENTY-FIVE CASES. By ALBERT VANDER VEER, M.D., Albany. From the *Transactions of the Medical Society of the State of New York*, 1888. 35 pages.

INTESTINAL OBSTRUCTION. WHEN SHOULD OPERATIVE MEASURES BE RESORTED TO IN INTESTINAL OBSTRUCTION? By ALBERT VANDER VEER, M.D., Albany, N. Y. 4 pages.

—Fifty-one of the operations reported in Dr. Vander Veer's paper were done by him and twenty-four by other operators in Albany. The pamphlet contains an extremely interesting account of the progress of abdominal section in that part of the country from the time of its tentative and dangerous beginnings to the present period of confidence and safety. As a whole it is a valuable contribution to the history of this operation, and what has been accomplished in Albany, taken with what is happening every day in other parts of the United States, seems to justify the statement of Dr. Vander Veer: "As America is first in much that pertains to progress in science and art, I am convinced that she will soon lead in the practice of abdominal surgery."

—In the discussion on intestinal obstruction at the last meeting of the Medical Society of the State of New York, Dr. Vander Veer gave the opinions contained in the four pages of this leaflet as to the time when medical treatment should be abandoned and operative treatment be instituted. The gist of them is that delay must be limited, and that an operation should be undertaken before shock and collapse appear.

CORRESPONDENCE.

Status of American Medical Schools in Europe.

To the Editor.

Sir: Yours of the 18th ultimo was duly received, but owing to my being absent in the South looking after Yellow Fever, I could not reply sooner.

Practically, the diplomas of no medical colleges are recognized in Europe. If the question was divided it could be answered much easier. As, for instance, the recognition of diplomas for the purpose of practice, or as a qualification prior to receiving degrees from institutions. Degrees of Harvard, University of Pennsylvania and Bellevue, receive recognition to a certain extent in some countries, but not in all. By a recent Act of Parliament, the Medical Registration Law of Great Britain has been changed, allowing the registration of diplomas from other countries. I am not advised as yet whether the law has gone into effect, or what diplomas are recognized. Am sorry I do not have time to look up the latter question more closely at present. If you have the files of the London *Lancet* during the past year you can ascertain the details with regard to the Act.

Yours truly,
John H. Rauch,
Secretary Illinois State Board of Health.

Springfield, Illinois,
October 4, 1888.

[This letter is an authoritative reply to a question asked by one of our subscribers. Editor.]

Skin Grafting.

To the Editor.

Sir: To an observer of the literature of the progress of practical surgery it is curious to see how frequently old, discarded practices are revived and proclaimed as novelties. Your recent editorial on "Transplantation of Skin From a Corpse" is a marked illustration of such a useless resurrection of a long defunct subject.

Many years ago, soon after the success of the process of skin grafting was announced, I tried grafting from the integument of recently amputated limbs, and also from the cadaver. The success of these grafts was quite equal to that from the living subject. But I soon discontinued the practice of grafting from the cadaver and from amputated limbs, and from any source but the patients' own integument, and publicly deprecated and condemned it as subjecting the patient to serious risks of specific infection.

You need not be troubled by the fear that the recent revival of this improper operation by a German surgeon "is likely to imperil the claim of our country for having originated it." I believe that I was the first who experimentally performed it, but would prefer to make the claim of having been the first to discard and condemn it.

I have successfully transplanted the skin of a rabbit to a raw surface that was denuded in a plastic operation on the face. In a noted case of cicatricial deformity of the face I successfully formed an entire upper eyelid from the integument of an anchylosed and useless finger that I had previously amputated from the patient's own hand.

I send to you herewith a copy of my pamphlet on skin grafting, which was originally published in the *Philadelphia Medical Times* about twelve years ago.

Yours truly,
Richard J. Levis, M.D.

Philadelphia,
September 25, 1888.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

Clinical Lecture.

TWO CASES OF ABDOMINAL CANCER.[1]

BY PROFESSOR S. JACCOUD,
PARIS, FRANCE.

Gentlemen: The study of two patients now present in our wards will enable me to direct your attention to the double obligation which the diagnosis of abdominal cancers entails, and to the great difficulties attending such diagnosis. The double obligation which I assign to the diagnosis belongs to all tumors: it is necessary to determine the *seat—topographic diagnosis;* and it is equally necessary to indicate the *nature—nosologic diagnosis.* The application, then, of this principle to abdominal cancers is but a particular case of a general rule; but it is perhaps in cancers of the abdomen that this application meets with the greatest difficulties.

It may happen that in the same patient the two parts of the diagnosis are equally easy or equally obscure; and it may also happen that one of the parts of the diagnosis is evident, while the other is entangled in very serious difficulties. This is the case with our two patients; in one of them, the patient who occupies No. 7 of Ward Jenner, the topographic diagnosis is so plain that there is little chance for mistake, while the nosological diagnosis remains almost doubtful; on the other hand, in the patient who occupies No. 28 of the same ward, the nosological diagnosis can be affirmed at first sight, while the topographic diagnosis continues to be obscure, if not uncertain.

[1] Delivered in the Hôpital Pitié, Paris, France.

Let us now enter into the detail of the facts. Our patient of No. 7 is a man 58 years old, a currier by occupation, who entered the hospital June 22, twelve days ago, because he had been for some time suffering with pains in the abdomen. He says, moreover, that he has grown somewhat thin, but does not complain of any alteration in his general health; the appetite is good, the digestion perfect, there is neither diarrhœa nor constipation. It is possible that he may have lost flesh, but he is still in sufficiently good condition; his features are animated, he is rather florid in the face, and there is nothing in this man to awaken the idea of a grave affection, much less of a cachectic disease. Proceeding to the examination of the abdomen to find the cause of the pains from which he is suffering, I detect at once by the sight, before making any palpation, a large swelling occupying all the region above the umbilicus, extending from one hypochondrium to the other. In the vertical direction the abnormal protuberance is seen to reach from the point of the xiphoid appendix to a finger's breadth above the umbilicus; there a deep fissure clearly separates it from the inferior region of the abdomen. This voluminous tumor strictly follows the respiratory movements, moving in its entirety during both inspiration and expiration, thus conforming itself to the rise and fall of the diaphragm.

Already to simple inspection this swelling, by reason of its volume and its configuration, gives the idea of a hard production; and, in fact, on palpation, the tumor is found to be everywhere of a compact hardness, this induration being almost uniform at all points. I say almost, for to be strictly exact I should add that it may in

this respect be divided into two parts, the one right, the other left; the right part is a little more bulging, and a little harder than the other. To percussion the tumor is absolutely and uniformly dull in all its extent; this dulness is continuous, without any line of demarcation, with that of the liver, whose upper limit does not seem to be displaced.

To sum up: there is a voluminous supra-umbilical tumor, obeying the movements of the diaphragm, not separable from the liver, presenting under exaggerated dimensions the form of this organ—such is the result of our investigations. The topographic conclusion is then plain enough; we have to do with a tumor of the liver. This conclusion is confirmed by the presence of a venous network, very highly developed over the abdominal wall; this network, which has been observed to augment rapidly during the days which have followed the entrance of the patient, is quite like that which is seen in advanced cirrhosis. The spleen is normal, the lungs and the heart intact. At the lower part of the left pleura certain light friction-sounds are heard; these are physical signs due to contiguity, which throw no light on the nature of the tumor: the latter has caused some perihepatitis, whence come the pains experienced by the patient; and, by spreading, the inflammation has gained the pleura and has produced a limited amount of dry pleurisy.

We come now to the nosologic diagnosis. What is the nature of this tumor of the liver? To answer this question, we get no hints from the pleural rubbing sounds, nor from the development of the subcutaneous network of veins; can we find any elements for a right judgment of the case in the physical characters of the tumor? Yes, doubtless; but here, if we are not careful, we shall be led astray, for the signs may deceive us. By the definiteness of its contour, by its regular convex bulging, this tumor immediately suggests the notion of a hydatid cyst. This first impression is corroborated by the absence in the patient of all digestive disorder, of all cachectic symptoms. We have really in this case, as much from a local point of view as from that of the general condition of the patient, the normal and typical picture of a huge echinococcus cyst; and I should certainly have halted at this diagnosis, which I believe to be wrong, if I had not followed the rule which I have for many years adopted in cases of this kind. Before pronouncing a positive opinion, and while still dwelling upon the resemblance of the tumor to a hydatid cyst, I have examined the inguinal region; I have found in Scarpa's triangle the glands on both sides augmented in volume, and greatly indurated. Upon this discovery, the absolute importance of which an experience many times repeated has taught me, I have at once rectified my judgment and formulated the diagnosis of cancer of the liver.

This is sufficient to indicate the importance which I attach to the state of the lymphatic glands in the nosologic diagnosis of abdominal tumors; and it is above all to the glands of the groin that attention should be given on such occasions. Last year, my colleague Troisier called attention to the alteration of the cervical and supra-clavicular glands in cancer of the stomach, and more generally, in abdominal cancers. This alteration is important, without doubt; but, in my experience, it is less frequent and more tardy than that of the inguinal glands. I have often, indeed, observed the differences which are easily noticed in the present patient; the inguinal Pleiades are completely and powerfully affected, while in the neck we can barely find on the left side a single gland that is plainly indurated; this gland, however, is not at all swollen, for its volume does not exceed that of a lentil. In many other cases also I have noted a more or less pronounced alteration of the glands of the groin, when a minute examination revealed the perfect integrity of the cleido-cervical glands. I maintain then the preponderant importance of the alteration of the inguinal glands as a sign of abdominal cancer, whether of the stomach or of any other of the viscera.

I will improve this occasion to correct anew a mistake in semeiology which has been committed with relation to the induration of the cervical glands in the course of pulmonary lesions. Chomel, and especially Grisolle, have each maintained that in these conditions the ganglionic induration is a certain sign of cancer of the lung. This proposition is too absolute; a long time ago, in my "Clinic of the Charity," I proved that this alteration may be linked to tuberculous lesions.

Since the entrance of the present patient till to-day, *i. e.*, for nearly a fortnight, we have not observed in him any change other than a rapid enlargement of the subcutaneous venous network of the abdomen; so that to-day, as at the beginning, my diagnosis is founded solely on the alteration of the glands of the groin. If this diagnosis is ultimately

confirmed, our observation will prove once more the semeiological value of these glandular indurations; if it shall prove to have been wrong, the signification of these lesions will be seriously shaken. To speak truly, I have no great anxiety on this score, for thus far this sign has never led me into error. I shall have finished with this first patient when I have indicated the number of the red blood corpuscles; this is 3,545,000, a number below the normal, doubtless, but which does not indicate a cachectic state.

The other patient is a shoemaker, 62 years old, who came to us five days after the preceding, on June 27. He occupies bed No. 28, Ward Jenner. He also suffers with a trouble in his abdomen, and it is not difficult to tell why; this man, in fact, is so emaciated, his complexion is so wan, without at the same time being straw pale, that the moment we knew that the seat of his disease was in the abdomen, we were at once certain that his disease was abdominal cancer.

I examine, and I find the confirmation of the nosologic diagnosis in the lymphatic glands; two groups are involved, but in very different degrees. In the inguinal regions all the glands are voluminous and indurated, and, moreover, perfectly painless. In the left side of the neck two glands are taken, between the two heads of the sterno-mastoid muscle; the upper is not augmented in volume, while the lower is as large as the end of the thumb, is very hard, and dips into the thorax by its inferior extremity.

In accordance with all these facts, and taking due account of the general alteration of the inguinal glands, I am certain that the intermediary glands are equally affected, whether in the mesentery, mediastinum, or in both regions at once. Keep this statement in mind, for we shall certainly have occasion before long to verify it. The blood dyscrasia is more marked than in the other patient, the number of the corpuscles being 2,385,100; but the profound cachexia would lead us to suppose a much more considerable diminution.

This patient, then, is certainly affected with an abdominal cancer; there is no chance for doubt. But where is the seat of this cancer? The topographic diagnosis meets here a real difficulty. For a long time this man has suffered with pain in his abdomen; but the pains have been vague, diffuse, without precise localization; as for pressure, it is not more painful over one spot than over another; these symptoms cannot enlighten us. What have been the other symptoms? Besides the emaciation and the enfeeblement, which cannot give much information, there is only one marked symptom, constipation, which has twice been so obstinate that his medical attendants feared intestinal occlusion. On the first occasion, the constipation lasted seven days. A brisk purgative was given on the eighth day, after many similar cathartic doses had been previously administered, and triumphed over the obstruction. The second period of obstruction was much more grave. It was not only by reason of the absence of stools that the attending physician inferred occlusion of the intestine, but also because this phenomenon coincided with rapid tympanitic distention of the belly, with a sharp exacerbation of the pains, and especially with the occurrence of nausea; it does not appear that there was vomiting. In this situation, the physician who attended this man in town naturally thought of the urgent necessity of an operation, and had him admitted into one of the surgical wards of this hospital. The repeated administration of energetic purgatives restored the normal stools, after which the patient was transferred to my service.

I have told you all the symptoms observed; are they sufficiently significant to reveal the seat of the lesion? Assuredly not. The first idea which they suggest is that of cancer of the intestine; and this idea is chiefly supported by the facts of obstruction twice noticed. But when a cancer causes sufficient stricture of the intestine to give rise to symptoms of occlusion, even temporarily, alternate periods of constipation and diarrhœa are observed in the course of the disease; moreover, the stools are bloody, or else glairy or muco-purulent. Now, all these symptoms are wanting, as we are assured by the daily examination of the fecal matters. On the other hand, in the supposed conditions of an intestinal cancer producing occlusion, palpation as a rule gives positive results when we take pains to examine specially the regions which are the seat of election of this tumor. These regions are, the rectum, the iliac fossæ, the loins, and the sub-umbilical part of the abdomen. But in this patient, these investigations most carefully practised are quite barren of results; the abdomen in its entirety is a little prominent, but in the regions indicated nothing is found—absolutely nothing.

I reject, then, the diagnosis of a localization of the cancer in the intestines; and, without allowing myself to be led astray by

the numerous lacunæ and symptomatic anomalies which seem to condemn this judgment, I believe that we have to do here with a case of cancer of the stomach, and I shall now search for the proof of this supposition in an attentive investigation of the epigastric region.

I note also that it is only in this region that we find anything abnormal; sonorousness to percussion is not complete; there is a shade of dulness, not only in the epigastrium, but also as far as the umbilicus. Over this region, especially midway in it, I feel a little too much resistance; this resistance is uniform, without projection or tumor. In consequence of these observations, I believe that there is a diffuse cancer of the anterior wall of the stomach, although the characteristic symptoms of this affection have thus far been completely wanting.

This diagnosis, I hardly need tell you, does not explain the accidents of intestinal obstruction; but, by reason of the extension of the dulness and resistance as far as the umbilicus, I think that the omentum is involved. It may be, also, that the mesenteric glands participate in the alteration, as I told you when calling your attention to the glands of the groin, and of the two cervical glands. Consequently, I refer the temporary intestinal occlusion to the compression exercised by certain peritoneal or glandular productions, and not to a lesion of the intestine itself. The bringing together of these two cases for purposes of comparison, seems to me to have a real utility, for it illustrates the serious difficulties which may attend both the nosologic diagnosis and the topographic diagnosis of abdominal cancers. It teaches us, besides, the means which we have at our disposal for triumphing over these difficulties, which I ought to tell you cannot always be surmounted.

The second of these patients will certainly succumb in the near future, and in his case, at least, we shall have an opportunity for verifying the exactness of the diagnosis which I have been led to make.

The patient died one month after the foregoing conference. The diagnosis was confirmed before his death by the development of certain very important additional symptoms, viz.: pain on pressure in the epigastric region; frequent vomitings, which were not bloody; and a well-marked jaundice, without appreciable modification of the liver itself. The icterus, accompanied by jaundiced urine and pale stools, was evidently due to compression of the bile-ducts by gastric or perigastric tumors. At a subsequent lecture, Dr. Jaccoud said:

The autopsy, only the principal particulars of which I shall here give in accordance with notes made by M. Duflocq, has revealed the following lesions: Cancer of the lesser curvature of the stomach and of the pylorus; mechanical obliteration by compression of the common bile-duct; retention of bile in the gall-bladder and in the liver; general invasion of the glands. The mesentery forms a block of cancerous nodules of various sizes. The glands of the lesser curvature of the stomach, and the prevertebral and pelvic glands are greatly swollen, and so are the inguinal, bronchial, and cervical glands. The intestine is sound throughout its whole length; the great omentum is intact. The spleen is diminutive. With the exception of the lesion of the omentum, which we expected to find and did not find, the diagnosis was verified in all its parts.

The nosologic diagnosis in the case of the first patient, founded solely on the alteration of the glands, has been also confirmed. The following note from M. Bourcy will inform you of the clinical phenomena which were developed after the last lecture, as well as the results of the autopsy.

During the month of July, the general condition remained quite good. In only the last days of the month the appetite diminished, then failed altogether; emaciation came on, there was every evening a little œdema about the ankles; in a word, the first symptoms of a cachexia of which the progress was thenceforth extremely rapid. In August, there were on two occasions abundant coffee-ground vomitings. From that time, the patient took almost no food, and the emaciation became extreme. The œdema of the legs was permanent; it spread to the thighs, the scrotum, the abdominal wall, and was accompanied with ascites. The excessive dropsical enlargement of the inferior members and of the abdomen presented a most striking contrast with the emaciation of the trunk, the arms, and the face. From that time, it was no longer possible to examine the deep abdominal viscera.

The inguinal glands remained to the end tumefied to the same degree as they were at the entrance of the patient; but the left cervical gland grew rapidly, and at the end of September it had attained the size of a large nut. In September, the cachexia became more and more pronounced, eschars formed on the sacrum, and the patient

succumbed on the morning of the 30th, after several days in which he was in a semi-comatose state.

The autopsy revealed the following alterations. On opening the abdomen, a considerable quantity of ascitic liquid escaped; the liver was found occupying all the epigastric region, completely covering the stomach, and literally stuffed with yellowish cancerous nodules of variable size; it was, therefore, the cancerous liver that formed the epigastric tumor felt during life. The determination of the primary centre of the cancer was quite easy. The *stomach* presented around the pylorus a sort of cancerous collar deeply excavated by jagged and sanious ulcerations, with conservation of the pyloric lumen. Here was the primary focus of the cancer, from which were disseminated by the absorbents numerous secondary nodules:

1. In the liver, which, augmented in size but not deformed, without large superficial and salient projections, was infiltrated with innumerable nodules; the latter were isolated in places, confluent in others, of volume varying between a hemp-seed and a chestnut, of a yellowish-white color, and trenching sharply on the substance of the liver, which was reduced to small dimensions. 2. In the glands of the hilum of the liver, which made strong pressure on the vena portæ, causing the ascites. 3. In the head of the pancreas. 4. On the inferior aspect of the diaphragm. 5. In the tracheo-bronchial glands. 6. In one of the cervical glands on the left side.

The lungs, the heart, the liver, the kidneys, the intestine, the genital organs, presented no secondary nodules.

—Dr. Wilhelm Zimmermann, of Greifswald, has been appointed Assistant in Anatomy in the University of Berlin, as successor to Dr. Klaatsch, who is to go to Jena.

—The enterprise and progressive spirit of Japanese surgeons may be inferred from the fact that the *Sei-I-Kwai* medical journal, August, 1888, contains a paper on "Three Successful Cases of Extirpation of Ovarian Dermoid Cysts," and one on the "Use of Cocain in Laparotomy for Extra-Uterine Pregnancy of 14 Months." So far as we know, this makes only the second case in which an abdominal section has been made with cocaine as a local anæsthetic. The first was reported by Dr. Roswell Park, in the *Medical Press of Western New York*, August, 1888.

COMMUNICATIONS.

HEMORRHOIDS AND THEIR TREATMENT.[1]

BY G. H. KIRWAN, M.D.,
WILKES-BARRE, PA.

The subject assigned for to-day's paper and discussion is one of such importance to practical physicians and surgeons that it might wisely have been assigned to some older and abler member than I; but, appreciating the honor you conferred in selecting me, I have done with the subject the best that, with a very limited practical experience, I could, viz—given you in what follows a compilation from some of the best authorities, and a *résumé* of some of the different recent methods of treatment, together with a comparison of the results obtained from each; and finally, have drawn conclusions therefrom.

Hemorrhoids, hemorrhoidal tumors, or the hemorrhoidal disease are medical terms used to define a diseased condition of the lower extremity of the rectum: the morbid condition that exists is almost always a dilatation or varicosity of the blood vessels; but these changes vary, according to the kind of hemorrhoidal tumor present, and will be described in defining the different varieties. Hemorrhoids are classified as *internal* and *external*, according as they are within or without the external anal sphincter. Such a division, however, is a merely arbitrary one. Of the so-called external hemorrhoid there are two varieties: the one a mere cutaneous teat or tab of redundant tissue so often observed about the margin of the anus; this variety, which is painless, may be present for years without giving any trouble, and is frequently simply the remains of the second variety after absorption has taken place; the second variety is a tense, bluish, smooth tumor due to dilatation alone, or to dilatation and subsequent extravasation of venous blood.

A more scientific classification of hemorrhoids, however, is one based upon the pathological changes that have led to their production. Considering them from this standpoint we have of internal hemorrhoids three distinct varieties, viz.: the Capillary, the Arterial, and the Venous hemorrhoid. The capillary hemorrhoid is really an erectile tumor (though never very large), composed of the terminal branches of the arteries and veins and the capillaries that unite them.

[1] Read before the meeting of the Luzerne Co. Pa. Medical Society, September, 1888.

It strongly resembles an ordinary small arterial nævus, and bleeds upon the slightest touch, hemorrhage being the chief symptom which distinguishes this variety. When it exists, hemorrhage always follows defecation, and this is the form ordinarily known as bleeding pile.

The arterial hemorrhoid is composed of a mass of freely anastomosing, tortuous, and varicose arteries and veins, bound together by connective tissue. The veins may be dilated into sacs or pouches, and the artery which enters at the base is of large calibre. Such a hemorrhoidal tumor is of large size and smooth surface, and is liable to inflammation, hemorrhage, and prolapse.

The venous hemorrhoidal tumor consists entirely at first of a simple varicose condition of the large veins beneath the mucous membrane of the rectum; later the veins undergo degenerative changes until a large, bluish, hard tumor is formed, which always comes out of the anus on defecation and assumes, from repeated exposure, a cutaneous character.

All the best authorities insist that these three varieties of internal hemorrhoids are well marked, and may exist at the same time, but they must be distinguished from each other in treatment.

The ordinary symptoms of internal hemorrhoids are a feeling of weight or fulness with a throbbing sensation in the rectum—in fact, a continual consciousness (not observed in health) that one has a rectum and anus, and that something is the matter with them. Bleeding upon defecation, and in some cases for a little time after it, is another symptom, not, however, constant in all cases. Other symptoms are: constipation; a feeling of weight and heaviness about the parts; a frequent desire to go to stool, with the belief that a full and free movement of the bowels will take place and relieve the sensation of uneasiness; and lastly, a protrusion of the hemorrhoidal tumors through the anal sphincter.

The feeling of weight and uneasiness hardly ever amounts to pain; if there is severe pain, it will usually be found after dilatation that a fissure or ulcer exists as a complication. When the hemorrhoidal tumors come down and are caught in the grip of the sphincter, there will be, of course, quite severe pain, which is immediately relieved by replacing the tumors within the bowel.

I have gone thus lightly and rapidly over the definition, varieties, pathology, and symptoms in order to devote most of my space to what I take it should be the principal part of all papers read before this Society, namely, treatment.

On the medical treatment of hemorrhoidal tumors or the hemorrhoidal disease, but a few words are necessary, as perhaps no case of well-developed internal hemorrhoidal disease has ever been cured by medical treatment alone, and but very few are even benefited by it, except temporarily. If hemorrhoids depend on congested or diseased conditions of the liver, or upon obstruction to the portal circulation from any cause, the relief of this condition by appropriate treatment will materially benefit the hemorrhoidal disease. In the relief of obstinate constipation, special attention should be given to the state of the bowels; the recumbent position should be assumed at stool; unstimulating food and, if addicted to its use, complete abstinence from alcohol should be advised. Locally, some astringent ointments or suppositories, and the injection into the rectum of very cold, even iced, water may be employed. These are about the usual remedies, but any or all of them as a rule frequently fail even to relieve, and, I repeat, rarely if ever effect a cure in advanced internal hemorrhoidal disease.

In coming now to the most important part of our subject, the surgical treatment of hemorrhoidal tumors for their radical cure, I have selected for consideration, from the dozen or more surgical procedures suggested and practiced, only four, viz.: 1. The Injection Method, sometimes called Kelsey's. 2. The Clamp and Cautery Method, called Smith's. 3. Mr. Whitehead's Operation. 4. The Ligature Method, with incision, Mr. Allingham's.

The injection method is performed as follows: An enema of hot water having been used and the patient having forced down the tumors into view as much as possible by straining, about five drops of a fifteen, thirty-three, or even fifty per cent. solution of pure carbolic acid is injected into the substance of the largest of the tumors. After this the tumor is replaced within the bowel. If by the second day after this injection no pain or soreness exists, a second tumor is similarly dealt with, and so on till all are treated.

Dr. Charles B. Kelsey, of New York, whose name is intimately connected with the treatment of hemorrhoids by injection, has materially modified his views as to the effectiveness of this method in all cases since the publication by him in 1885 of 200

cases treated in this way. He says in the latest edition of his work on Hemorrhoids, "that he has since had pain, marginal abscess, ulceration and fistula follow its use," and that "the treatment by injection may not result in a radical cure." He further says: "In a word, the question narrows itself down to this: on the one hand we have a method safe, certain, and practically painless (the clamp and cautery method), but which involves the administration of ether and the performance of what the patient dreads —a surgical operation and a certain confinement to the house for a few days; on the other hand, a method which involves fully as much of an operation as the other, only more quickly performed, and without ether, and which is neither radical nor certain in its results." And he further says: "All the patient actually gains in the most favorable case is the avoidance of a safe operation, which he fears, to submit to an uncertain one, which he does not fear because of his ignorance."

Dr. Bodenhamer, of New York, an eminent specialist, says: "Never having treated a case of hemorrhoids by the injection method, I have therefore no experimental knowledge of it; but of its bad sequelæ I have abundant experience and proof, having since 1875 treated thirty-five cases of patients who had submitted to this operation, but who were not only not cured but much injured in various ways by it. The most of these cases had anal abscesses and anal fistulæ to follow it; others had anal fissure to result from it; others again had a thickening and induration of the coats of the lower portion of the anal canal, which interfered greatly with the normal action of the external sphincter. In some of the cases the operation was followed by extensive sloughing of the cellular membrane in the vicinity of the tumors, and by persistent hemorrhage, and others have had hard nodules follow the treatment. In all these cases, as far as I could learn, carbolic acid in different degrees of strength was the agent which had been used. In 1875 I made the following remarks in the New York *Medical Record:* 'The method of treating hemorrhoidal tumors by injecting them with coagulant hemostatic and cicatrizant solutions is of quite recent date. From the great excitement recently manifested by a few fanatics concerning this method, some were inclined to raise the cry "*eureka*," or led to believe that it, like Aaron's rod, was destined to swallow up all other methods. It may be remarked, however, with regard to this new candidate for fame, that as yet it has no status in surgery, and it is questionable whether it ever will prove a real benefit to, or an advancement in, that science as it regards a safe and certain remedy in the treatment of hemorrhoids especially.'"

Mr. Allingham says of this method of treatment: "I have tried the injection plan in many cases. The result was generally much pain; more inflammation than was desirable; a lengthy treatment; and the result doubtful — *certainly not* a radical cure." And again: "All attempts to destroy vascular growths by causing coagulation of blood or inflammation in them while they are not shut off from the general circulation *must be fraught with danger.* You can have no guarantee that the coagulum may not break down and minute particles of dead tissue find their way into the vascular or lymphatic systems and result in embolism, or pyæmia, or both."

The clamp and cautery method is a well-known form of treatment which has many eminent advocates. The name of Mr. Henry Smith, of London, is most frequently associated with it. "In its performance each pile is seized by a volsellum and drawn well down. The clamp is then applied so as to embrace its base; the portion above the clamp is cut off with scissors, and the stump cauterized, usually with a Paquelin instrument." Mr. Allingham says of this operation: "In my opinion it has little to recommend it: as regards danger to life (after all, the issue of the *greatest* moment), as far as my most careful researches have led to a conclusion, it is quite six times as fatal as the ligature properly and dexterously applied; there are, moreover, these disadvantages: the burning causes very great pain after the operation, especially if the skin is involved; secondly, hemorrhage is more likely to occur than after the best mode of operating, greater sloughing of the parts takes place, and a longer period is required for healing."

Dr. Kelsey, of New York, gives as his views a directly opposite opinion; he says: "I prefer the clamp and cautery to all other radical measures, as being less painful and giving a quicker recovery."

Mr. Whitehead's operation is a plastic operation for the radical cure of hemorrhoids of recent date, it being little more than a year ago that its originator, Mr. Walter Whitehead, of London, first called attention to it. It is performed as follows: The pile-bearing mucous membrane is dissected off from the skin border of the anus

all around, after the manner of performing total extirpation of the rectum (except, of course, more superficially), and all the pile-bearing area removed. All bleeding vessels are twisted, and the mucous membrane above the pile-bearing surface is brought down and stitched to the skin border. Dr. Robert F. Weir, of N. Y., has performed this operation for hemorrhoids many times, and I believe gives it his preference in all suitable cases. Mr. Whitehead himself claims many points of advantage for it over all other surgical procedures, but those generally conceded are that the hemorrhage is trifling, the union is primary, and retention of urine very rare. For those who prefer the very latest in the surgical treatment of hemorrhoids, this operation is here given.

The *Pittsburgh Medical Review*, in a late comment upon Mr. Whitehead's operation and Dr. Weir's method of performing it, says: "It is certainly a much more surgical method than the old ligature operation, but to all appearances offers no special advantages beyond the satisfaction it affords the surgeon in performing a plastic operation, and freedom from subsequent retention of urine." Mr. Allingham's objections to this operation are that it is in most cases a more formidable undertaking than the existing condition warrants; that the length of time required for the operation, and the excessive hemorrhage as compared to the ligature method, make it inferior to other methods in most cases.

We come now to the consideration of what I believe from a careful study of this disease is *the* operation for the radical cure of hemorrhoidal tumors; although, of course, it will be understood that no one method can be applicable to all cases. *Exempli gratiâ*, take the small capillary hemorrhoid described; one application to it of fuming nitric acid, properly made, cures it forever. We will now consider the treatment of hemorrhoidal tumors by the ligature; and when I speak of the ligature operation I mean the operation by incision and ligature known as Mr. William Allingham's. He thus briefly describes it in his works:

"After the patient is etherized and placed in position, gentle but complete dilatation of the sphincters is done." (I desire here to impress upon all who do not know it from experience, the *very great importance* of gentle but entirely complete dilatation, and consequent temporary paralysis of the sphincters before any operative interference.) "The hemorrhoidal tumors are brought down one by one; then, with a pair of sharp scissors, the pile is separated from connection with the muscular and submucous tissues. The cut is made in the sulcus, or white mark which divides skin from mucous membrane. This incision is carried a distance up the bowel until only an isthmus of vessels and mucous membrane is left; a strong silk ligature is placed at the bottom of the groove, and, the assistant drawing the pile well out, the ligature is tied high up at the neck of the tumor as tightly as possible. A portion of the tumor may now be cut off, or the whole returned within the bowel. After all tumors are thus treated, a suppository of morphia is placed in the rectum, a pad of antiseptic wool is placed over the anus, and a tight **T** bandage completes the dressing." This briefly is the ligature operation, and it probably has effected more cures of hemorrhoidal disease than all the other surgical procedures combined.

That this operation is grounded upon a sound surgical basis no practical surgeon can dispute. Mr. Allingham (than whom there is perhaps no greater authority living) has performed this operation in private and hospital practice more than two thousand times with but three deaths, and he says of it: "I do not think in the whole range of surgery there is any procedure worthy of the name operation which can show a greater amount of success or smaller death-rate than the ligature of internal hemorrhoids." And again he says: "It is both the safest and quickest operation to perform in all cases of well-formed hemorrhoidal tumors."

Dr. Bodenhamer, of N. Y., says: "I have yet to encounter my first serious accident."

Dr. Gross says: "The operation is as simple of execution as it is free from danger and certain in its results."

Recognizing that a paper of this kind should contain something more than a mere compilation from books accessible to all of us, and being able to give very little from personal experience, I took the trouble to obtain by correspondence the following opinions upon the subject from eminent men, which certainly embody more recent views as to treatment than any of the text-books.

I submitted, to the men whose names follow, the following five questions on mooted points in the surgical treatment of hemorrhoidal tumors. I will read you the first question and their separate replies.

The first question was: "To what extent do you carry out in your surgical treatment of hemorrhoids the principles of antisepsis as ordinarily employed in operation wounds?"

1. "Only in having my instruments and the water used aseptic."—D. Hayes Agnew, Philadelphia.

2. "General cleanliness."—Thomas G. Morton, Philadelphia.

3. "Thorough cleansing before, and frequent irrigation after operation, with bichloride solution."—Louis McLane Tiffany, Professor of Surgery, University of Maryland, Baltimore.

4. "I treat antiseptically as far as the nature of locality permits—using corrosive sublimate cloths, iodoform, etc."—John H. Brinton, Professor of Clinical Surgery, Jefferson Medical College.

5. "To its fullest extent."—Joseph D. Bryant, Professor of Clinical Surgery, Bellevue Hospital Medical College.

6. "I use all necessary antiseptic precautions."—Dr. William Bodenhamer.

7 and 8. Mr. Allingham, of London, and Dr. Kelsey, of N. Y., in reply to my queries kindly mailed me their latest books from which their views are to be taken. Neither refers to the antiseptic principle at all in his book.

9. "To obtain as much cleanliness as is possible in this part of the body—bichloride solution externally and Thiersch's solution within the rectum and anus."—John A. Wyeth, N. Y.

The second query was: "Do you rely entirely, or at all, on cocaine or any form of local anæsthesia in your surgical procedures for the cure of hemorrhoids?"

1. Dr. D. Hayes Agnew, of Philadelphia, says: "No."

2. Dr. Thomas G. Morton, Surgeon to Pennsylvania Hospital, says: "No. Often do not use anæsthetic for internal, but always for external hemorrhoids."

3. Dr. Louis McLane Tiffany says: "Compression by clamp."

4. Dr. John H. Brinton says: "I have employed local, but prefer general anæsthesia from ether inhalation."

5. Dr. Wm. Bodenhamer, of New York, says: "I now use cocaine as a local anæsthetic in all cases in which general anæsthesia is not *particularly* indicated. I have found it of much value."

6. Mr. William Allingham, of London, says "No. It is only of use when mucous surfaces are to be operated upon — as cocaine does not sufficiently deaden the sensibility of the skin to make it of practical service."

7. Dr. John A. Wyeth says: "I have used cocaine (4 per cent. solution), but lately have found that most patients do not suffer more from the carbolic mixture than from the distention by cocaine. When I do the ligature operation, ether narcosis."

8. Dr. Charles B. Kelsey says: "In minor operation the drug used hypodermically is perfectly satisfactory. In larger ones it is not to be relied on absolutely, and may have to be supplemented with ether."

9. Prof. Joseph D. Bryant says: "I have done so, but do not make it a practice—can be done easily if case be a simple one."

The third question asked was: "Are you convinced from experience of the permanency of the cure of hemorrhoids by the injection method of treatment?"

1. Dr. D. Hayes Agnew: "Yes, in well-selected cases."

2. Dr. Thomas G. Morton: "By no means."

3. Dr. L. McLane Tiffany: "My experience does not justify an opinion."

4. Dr. John H. Brinton: "I have seen cases operated on by others where the hemorrhoids still existed, but I knew nothing of the extent of operation. I have seen the saddest results in the way of sloughing from the injection of carbolic acid. If used at all, believe it should only be when pile is thoroughly clamped before injection. I would only resort to this method in exceptional cases."

5. Dr. Joseph D. Bryant: "Am convinced that in selected cases this method causes as good results as any; but it cannot produce better final results than tying."

6. Dr. W. Bodenhamer: I have given Dr. Bodenhamer's views under the description of this operation, in which he condemns it in severe and measured terms.

7. Dr. C. B. Kelsey says: "It is neither radical nor certain in its results."

8. Mr. William Allingham: "The injection of carbolic acid into the interior of piles may in some instances stop the bleeding for a time, yet it cannot and does not in any way remove the tumors."

9. Dr. John A. Wyeth: "I believe injection will cure a hemorrhoid thoroughly injected. The process of cure demands inflammation (preferably sub-acute) and cicatrization (or shrinking)."

The fourth question was: "Did you ever know personally of a permanent cure of internal hemorrhoids by simple dilatation of the sphincters alone?"

This query was asked because in this city during the early spring and summer this method was practiced by a notorious quack on many people, who, after submitting to it, believed themselves cured; but in several of

them, to my personal knowledge, recurrence has taken place—not, however, until the disappearance of their former medical attendant and their cash. This method has some legitimate foundation, however, having been advocated by Verneuil and other eminent French surgeons.

1. Dr. D. Hayes Agnew says in reply to it: "No."

2. Dr. Thomas G. Morton: "No."

3. Dr. L. McL. Tiffany: "No experience."

4. Dr. John H. Brinton: "I cannot answer positively."

5. Dr. Joseph D. Bryant: "Have known relief to follow, but not a permanent cure."

6. Dr. Bodenhamer: "I never did."

7. Dr. John A. Wyeth: "No; and despite Verneuil's statement, cannot believe it possible."

8. Mr. Allingham: "It will give wonderful relief in selected cases."

The fifth and last question was: "What surgical procedure do you consider the safest, most generally applicable, and yielding the best permanent results in the surgical treatment of hemorrhoids?"

1. Dr. D. H. Agnew: "When large, I prefer the ligature."

2. Dr. Thomas G. Morton: "My universal practice is the ligature for internal and the ligature and excision for the external variety."

3. Dr. L. McL. Tiffany: "I probably use clamp and cautery as often as any other."

4. Dr. John H. Brinton: "I prefer ligation of internal hemorrhoids. I use a fine linen cord soaked in sublimate solution, and when the hemorrhoid has a partial cutaneous covering I form a track with knife in the skin covering, to divide nerves, and thus avoid pain after the old method."

"My opinion is decided in my preference for this method."

5. Dr. Joseph D. Bryant: "Ligation with cat-gut."

6. Dr. Bodenhamer: "I consider ligation, if judiciously and properly applied, the simplest, safest, most certain, and most effectual of all known methods. It has the recommendation, the advocacy, and the indorsement (with but few exceptions) of all the leading surgeons of Europe and America."

7. Dr. John A. Wyeth: "Allingham's operation—ether narcosis."

8. Dr. Charles B. Kelsey: "I prefer the clamp and cautery to all other radical measures, as being less painful and giving a quicker recovery."

9. Mr. Allingham: "Ligature with incision, for reasons given under the description of the operation."

From a careful review of the best recent works on the subject, from a very limited personal experience, and from the very able opinions obtained by correspondence and just read to you, I have drawn the following conclusions:

1. The principles of antisepsis should be carried out (as far as possible) in this as in all other surgical operations.

2. Local anæsthesia is not to be relied upon in surgical procedures for the radical cure of hemorrhoids.

3. The injection method of treating hemorrhoidal tumors is not reliable, not safe, and not comparable with safer and surer methods.

4. Simple dilatation of the sphincters alone probably never cured a case of well-developed hemorrhoidal tumors.

5. Mr. Allingham's operation by the ligature with incision is beyond a doubt the safest, most generally applicable, and yielding the best permanent results in the surgical treatment of internal hemorrhoidal disease.

PREVENTION OF CONCEPTION.

BY THOMAS A. POPE, M.D.,
CAMERON, TEXAS.

I accept the wise and timely suggestion in the REPORTER, Sept. 15, 1888, to discuss the prevention of conception, because the subject is one that comes almost daily before every physician; and, as there has not heretofore been any extended public discussion of it, every physician has heretofore had to deal with the matter as seemed best to himself, without advice or help from his professional brethren. In other matters we are greatly aided by the recorded experiences and conclusions of others, but on this subject we get no such help.

For myself, I have some decided opinions about the prevention of conception, and if I am wrong I would be grateful to be set right. One man, however wise, might easily come to wrong conclusions if left to himself, but a large body of educated, fearless and conscientious gentlemen by the thorough discussion of any question are certain in the end to be right.

I believe this world would be better and our people happier if the child-bearing period of woman began at twenty-two and ended at thirty. If such were the case, there

would be less poverty, ignorance, crime and disease, and of course more intelligence, refinement, comfort and happiness. The vital statistics of the United States have never been gathered and collated as they should have been in the past, and ought to be in the future, so there is no way of arriving at exact conclusions concerning the increase of population. But the census of 1880 showed nearly three-fourths of a million net gain from births. This would show a net increase of about one and one-fourth per cent. per annum. But even if the net increase of our population from births and immigration should amount to two per cent. per annum it would be many years before the conditions that Malthus feared in Europe would obtain here. Malthus perhaps forgot when he wrote that almost one-half of the world was unpopulated, and that ages must elapse before the whole would be settled as densely as some parts of Europe were sixty years ago. But while we need not perhaps urge the same reasons now that Malthus did for limiting the population, the time will soon come when the question: Wherewith shall all these people be clothed and fed? will be a vital one. There are no new worlds to conquer. Every inhabitable part of the globe now has its tenants, and in many portions of it the population is now so dense that mere existence is a struggle, and the population is everywhere increasing. The laws just passed by Congress restricting Chinese immigration and prescribing the return of improper immigrants from Europe constitute the beginning of a struggle for the survival of the fittest that henceforth will not cease as long as mankind shall continue to multiply and replenish the earth.

Let us now examine somewhat in detail some of the reasons against too frequent conception. And, first, it often causes the death of the preceding child. It is a very common occurrence for the wife to become pregnant within from two to six months after confinement, and then of course the little babe is weaned and must be artificially fed. I cannot state accurately how many of children so weaned and artificially fed die; but I am certain that at least one-half of them die in infancy, and half of those that survive are neither strong nor healthy.

It will, of course, be understood that I am speaking of poor people, where the wife is compelled to work and cannot procure for the child the things it needs or give it the attention and care it should have. And I here remark that very frequent conception is now mostly confined to the poorer class. The rich, in town and country, already limit the number of their offspring; but for a different reason, perhaps, from that for which I would limit it among the poorer people. I have no doubt that most of the criminal abortions occasionally seen in the country and so often occurring in the cities are due, not to the fact that no children are wanted, but to the fact that the mother feels she cannot educate and care for so many, and becomes desperate and commits a crime rather than bear children she knows cannot be adequately provided for.

There are very many women who ought not to bear children because their children are likely to be diseased in body or mind, and, if they survive childhood, will be a burden to themselves and society. This is a most important reason, and the subject deserves a chapter to itself; so I shall only advert to it here, and leave its further consideration to some future time or other writer.

In the year 1880 there were 5646 deaths from child-birth in the United States. The number of women who died that year in child-birth was about equal to the number who died from pneumonia within the child-bearing period. If it were possible to permit only those to become pregnant in whom no contra-indication exists, the death-rate in child-birth, instead of being nearly four in each thousand, would be *nil*. Most women who bear many children become prematurely old. This is rather because of the mental anxiety and worry of watching over and caring for so many children than from the effect of child-birth, but this with its attendant troubles is no doubt an important factor. As a rule, women at forty, who have given birth to not more than three or four children, are, other things being equal, in better health and every way better preserved than the women who have given birth to from six to ten. I cannot think that the Creator intended that woman—the best and fairest part of His handiwork—should become a mere machine for the propagation of the species; but such she would become if she were perfectly healthy herself, and had a healthy husband, if no means were used to limit the number of her offspring. Such a woman would be confined almost exclusively to her home, social intercourse with friends would be limited, and, however bright an ornament of society she might have been, it would know of her only through the birth and perhaps death column of the daily paper. Some of her children would be neglected, and she could

give to none of them the attention she could have given if the cares of maternity had not been so many and so exacting. The health of children depends greatly on a mother's care, and if she has two or three, or even four children, she could look carefully after each child and protect them all from disease. From the reasons given, it seems certain that prevention of conception, if judiciously practised, would lessen the death-rate of both mothers and children and almost eradicate many hereditary diseases; our offspring would be healthier and happier; idiocy would be unknown, and insanity infrequent.

Now let us look for a moment at the economic side of this question. To clothe, feed and educate his offspring properly would require an addition to the parent's income of at least $400 at the birth of each child. That is, if man and wife could live comfortably on, say, $800 a year, then one child would call for $1200 for the three—a second child $1600 for the four, and so on. What proportion of our population would be able to meet the increased expenditure so essential to making of the child a good and useful member of society?

There are to-day in the United States about 9 millions of families, averaging about seven persons to each family. Now I think it fair to assume that the net average income of over one-half these families would fall below $800 per year, and perhaps even less than $600. One-half of the families of the United States cannot properly feed and educate their children, and with a majority of them it is a struggle to maintain an humble home with few comforts and no luxuries, and the little ones must at the earliest possible moment become breadwinners in order to eke out their parents' scanty income. Does it not seem like the greatest cruelty for a man and woman, with no visible means of support, who live by the proceeds of their daily toil, which is perhaps barely sufficient for their own needs, to bring into the world a large family when they must know that every child has no heritage but one of poverty, ignorance and toil? When they know that these children in the period of childhood and youth, when in need of judicious care and training, must begin a life of labor and mental darkness with but little promise of any lightening of the load which their very existence has forced upon them? The men who lead in every sphere of life, in politics, in war, in science, or in religion, do not, as a rule, lead because they have bigger or better brains than many of their fellow-men, but rather because they had more judicious training and better opportunities to improve and cultivate the talents given them by nature. I am sure that thousands of men and women sleep in unknown graves to-day, who, if they had had early and kindly care and been given the proper opportunities, would have been famous in some line, and would have had marble monuments instead of pine boards to mark their final resting-place. If the number of children were limited, better opportunities and better care would be for all, and all could have a start in life so fair that success would come to all who deserved it. Again, crime would be lessened by limiting the number of offspring, because there would be less offspring of vicious parentage and, as each child could be better educated and have more comforts, there would be less temptation to begin, as most criminals do, a life of crime in youth or childhood. I have recently read an article in the *Amer. Journal of Obstetrics* which dwelt considerably on the "crime for which Onan was so severely punished." If the distinguished author had read his Bible before he wrote the article, he would not have said "The boastful citizen (of to-day) . . . does not hesitate to commit the crime for which Onan was so severely punished," because he would have seen that Onan was punished for attempting to evade the consequences of a custom which would itself be regarded as indecent to-day. If the author of the article above quoted means that "wasting seed" is a crime, then a man would commit a crime every time he had intercourse with his wife after she became pregnant, for his seed would then certainly be wasted. And it would be a crime to have intercourse with her at any period when she could not become pregnant. To prevent being branded as a criminal, a man would have to possess a most thorough and scientific knowledge of the physiology of generation, and govern himself accordingly. I say there is no law, human or divine, written or unwritten, that forbids the prevention of conception when any valid reason for the prevention exists. And, in this, I am not saying anything in favor of licentiousness or providing a way to cloak immorality. I am speaking of persons lawfully bound together in wedlock.

Paul, in his letter to Timothy, says that a man who does not provide for his family is worse than an infidel. Then, would it not be a crime against society and a sin against religion to beget children when one knew beforehand that he could not provide for them?

The Editorial in the REPORTER of Sept. 15 suggests several other points that deserve attention, and I hope others will supply what I have omitted, which yet ought to be said. For the present I will content myself by calling attention to the following remarks of Dr. J. Ford Thompson, at a meeting of the Gynæcological Society of Washington, D. C., on May 28, 1888.[1] "A great deal has been said and written on this subject that is not true either scientifically or in fact. There is no proof that preventive measures do any harm. Over-indulgence may affect the male injuriously, but self-limitation does not. What difference physiologically does it make whether the emission takes place in a condom or in the vagina? None, because the sensations are the same and the effect on the male is the same. The most common method is withdrawal, and what difference does it make? There is more room for unpleasant effects than from emission in a sheath, but he doubted any deleterious effect. The sexual act is not completed, but the emission takes place, consequently he doubted whether this method was attended with any injurious effect upon the male.

"Now, on the part of the female, let us consider the effects of these methods upon her organism. With the use of the condom the sexual act is completed. He did not believe in the many theories of the part the female organ takes in coition, such as the descent and opening of the cervix and the aspirating effect of the uterus. The method of withdrawal may occasionally injure a female, but such cases are not as frequent or numerous as we are led to suppose. The orgasm in the female is not hastened by the emission of the male, but precedes it. If this is true, then withdrawal is not injurious to her; and if it is not true, the only effect is to leave her unsatisfied. The use of the hood by the woman is practically the same as the use of the condom by the man, and does not interfere with the complete act of coition. So far then as mechanical appliances are concerned, there is no proof that they do any harm to either party and their evil effects have been greatly exaggerated. Withdrawal is the only case where physical injury may result, and even this is very doubtful.

"The cold-water douche may have a deleterious effect upon the female, but it is questionable whether tepid water or water impregnated with carbolic acid or astringents injures her. It cannot be proved that any of these methods is injurious."

A SEVERE RAILROAD ACCIDENT.

BY T. F. McGEE, M.D.,
TRINIDAD, COLORADO.

J. T. Link, thirty-two years old, brakeman on the D. T. & F. W. R. R., met with injuries external and internal; the latter of which were very severe and accompanied with great shock. On September 9, while sitting on the side of freight train, running at usual speed, he was looking back at a hot box, when he was struck on the left side of the head, while passing through a narrow bridge, splitting his ear, and throwing his body through the bridge to the ground, some distance below. He was brought to this city, some five hours later, and by instruction of Supt. Grover of said road, he was placed in my care for treatment. I was ordered by telegram from Chief Surgeons Drs. Beall and Adams, of Fort Worth, Texas, to forward the injured man to the hospital, if his condition would admit; but, owing to his severe shock and the nature of his injuries, I declined to do so.

He was struck on the left side of his head, and his right shoulder, and almost the entire right lobe of his liver, together with a considerable portion of the dorsal spine, were so severely injured as to cause ecchymosis, which appeared several days afterward, showing the deep nature of the internal injuries. There was also slight hæmatemesis, and slight hemorrhage from the cranium—not from the split ear. When I first saw the patient, his pulse was small and feeble, but regular; inspirations about fourteen, every breath causing an agonizing pain. I gave him a hypodermic injection of sulphate of morphia, and ordered hot applications to the injuries, and left small doses of morphia to be given by the mouth, as might be necessary to keep him quiet during the night, leaving word to let me know in case he became restless.

I visited the patient next morning, found his pulse seventy-two and very full, and that his bladder had acted once during the night. In the afternoon his pulse ran up to ninety-six; his temperature was 102° F., and he was suffering greatly. I ordered Rochelle salts to move his bowels, and hot flax-seed poultices sprinkled with chloroform liniment to be put on over the entire injured surface, as hot as the patient could bear. Under the above treatment, he became more quiet, his bowels moved freely, his pulse came down to normal, and his temperature fell to 99° F. But these favor-

able symptoms lasted only a short time, when he began to suffer as much as ever; the hot poultices were continued; and as long as they remained hot and he was kept under the influence of very large and often repeated doses of morphia, his sufferings were to some extent bearable.

The fourth day he began to have hemorrhage from the bowels, averaging from eight to sixteen operations per day. From the fifth to the sixth day from the time he began to pass blood from the bowels, the discharges assumed the character usual in intestinal catarrh. Dr. Omstead of this city saw the patient with me the third day after the accident; and, on account of the high-colored urine and the full pulse, suggested five-grain doses of antifebrin every four hours.

The suggestion was a good one. Under the influence of antifebrin the kidneys acted much better, and the patient rested much easier.

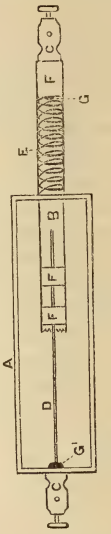
His temperature never exceeded 102° F.; and his pulse never ran over a hundred. His urine was high-colored, and his suffering was intense. At times he had stertorous breathing, which of course alarmed me, with frequent and severe hiccoughing, which did not lessen my fear; and the above symptoms lasted from eight to ten days.

The patient is now able to walk about with his arm in a sling, as he still suffers more or less pain under the right shoulder-blade. He informs me, since his recovery, that he has no recollection of anything during the first five days succeeding his injuries.

SIMPLE ELECTRICAL APPARATUS.

BY SUMNER GLEASON, M.D.,
CARTHAGE, NEW MEXICO.

Electricity is admitted to be a potent factor for good when properly used in some of the derangements of the human system. Here there is a large field open for research and a rich harvest to be gathered. The medical profession is just beginning to learn how to make use of this agent; but a large number of physicians are still in ignorance as to the methods of operation or the results to be obtained. This is in great part due to the expense of the apparatus necessary. Now a convenient galvanic battery for office work can be made for a very few dollars, and any physician of a mechanical turn of mind will take pleasure in putting it together. Zincs and carbons with attachments can be obtained from any manufacturer of electrical apparatus. These should be attached to a thin board, so that they can be raised from the cells when necessary to add more water. Cells can be made of old bottles. To cut off the tops, place the bottle in the corner of a box which holds a steel wheel glass-cutter at the place at which it is desired to cut the bottle; turn the bottle until the lines meet; then heat the line in a flame for a moment and plunge the bottle in cold water; the top will then split off neatly in the line marked. Paraffine the inside of the jar for about an inch from the top. The carbons and zincs should also be paraffined above the level of the fluid, in which they may remain constantly. The fluid consists of a saturated solution of bichromate of potash and muriate of ammonia, the latter being pure. Thirty-six cells will give enough current to commence with, and, after becoming familiar with its effects, as many cells can be added as are desired. A milliampere-meter is not a necessity for the novice. He will learn more by experimenting on his own person; but, of course, cannot expect to obtain as good results from his battery.



A. Wooden box.
B. Glass tube filled with water.
C C. Binding-posts.
D. Straight copper wire.
E. Coil of copper wire.
F F F. Corks.
G G'. Screws.

Above is a drawing of a rheostat which can be made for a few cents. This is indispensable where there is no arrangement for increasing the current one or two cells at a time. It serves the purpose of increasing and decreasing the current without shock to the patient; it can be attached anywhere in the circuit, and should always be used where a steady current is passed through a sensitive part. All that is necessary to buy is two binding-posts and screws, costing ten cents each. A glass tube can be made of an

ordinary glass syringe, cutting off the end with a file. In one end fit a cork to which should be attached a binding-post, the screw passing through the centre of the cork. To the head of the screw attach a copper wire coiled so as just to fit in the tube. This should be so that it can be removed easily and the tube filled with water, which should be done before each sitting, as the water decomposes rapidly. In the other end of tube, place one or two corks. In one end of a small wooden box cut a hole just large enough to allow the tube to slide easily. At the other end attach a binding-post, and to the screw-head on the inside a straight copper wire to pass through the centres of the corks FF. Now a current of electricity passing through this wire meets the resistance of the column of water, and as the tube is pushed in this resistance grows less, until the wire is in contact with the screw G; the current is then at its maximum intensity. The tube should of course be pulled out before the current is broken.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, October 4, 1888.

Dr. T. M. Drysdale in the Chair.

Dr. Theophilus Parvin exhibited a specimen of

Extra-Uterine Pregnancy,

removed by Mr. Tait in the latter part of August. Pregnancy was supposed to have advanced six or seven weeks. Rupture had taken place two days before the operation. The patient was doing well when Dr. Parvin last heard of her condition, four days after the operation. He thought that Mr. Tait was really the most wonderfully expert surgeon in abdominal diseases he had ever seen. In his work no antiseptics are used; perfect cleansing of the hands is accomplished with soap, water, brush and towel; the abdomen is perfectly cleansed; the incision is through the skin and underlying tissues; hæmostatic forceps are used if necessary, but frequently are not required. Forceps are used to take up the tissues as the peritoneum is approached; the peritoneum is raised almost an inch, so that there is no risk of injuring anything beneath the membrane; the peritoneum is then cut into. The moment the incision is made, one or two fingers, or rather the index finger and the thumb, are introduced. In the case just referred to, the diagnosis was not positive, only probable, before opening the abdomen; but as soon as Mr. Tait had introduced his fingers into the abdominal cavity, he said that it was a case of extra-uterine pregnancy with rupture of the tube. Probably five minutes were required to bring up the ruptured cyst and ligate the tube with the Staffordshire knot. After removing the tube and ovary, water was poured in through a funnel to which was attached a rubber tube with a nozzle. The metal nozzle was pushed around in all parts of the abdomen, so as to wash out all of the clots. In this particular case, two pitcherfuls of water were used. A drainage-tube was introduced, and three stitches used to close the abdominal incision. This patient did not have a temperature above 100°, and when seen three days later her recovery seemed almost absolutely certain.

Dr. Parvin exhibited the following instruments:

The Axis-Traction Forceps

of Dr. Stephenson, Professor of Obstetrics in the University of Aberdeen. The forceps closely resembled the Simpson forceps, being only a little longer and the pelvic curve greater. The traction is hooked on in front of the lock after the forceps is applied.

Dr. Wm. Goodell thought that after seeing Stephenson's forceps, he could justly lay claim to all priority in the axis-traction device. Many years ago, in his work at the Preston Retreat, he found that his back so often gave out while making axis-traction with his left hand on the lock of the ordinary forceps, that he sewed a stirrup to the end of a leather strap. The other end of the strap he wound around the forceps handles near the lock, and in the stirrup he placed his foot. He usually hung the strap so near the floor that his heel rested on the latter, the traction force being made merely with the toes or ball of the foot. He thought Dr. Price had probably seen this impromptu device hanging on a gas-fixture in the lying-in room of the Retreat. Of course the woman lay on her back with her nates drawn over the edge of the bed.

Dr. Price remarked that he had seen the device spoken of by Dr. Goodell.

Dr. B. F. Baer read the following report of two cases of

Multilocular Ovarian Cystoma

of unusual size and very rapid growth.

Mrs. X. was sent me by Dr. J. A. Clark, of Bedford, Pa., and on July 31 entered my private hospital. She is 28 years old; married; has had two children after normal labors, the youngest being six years of age. About nine months previous to this date she was attacked with severe pain in the right ovarian region and was confined to bed for several weeks. Her menses had always been regular, but at this time the flow was profuse and continued two weeks. Soon after this attack of pain and metrorrhagia she noticed a swelling in the painful region, on the right side. She rapidly increased in size and began to lose flesh, and occasionally to have attacks of pain and metrorrhagia similar to the one just noted, the flow on several occasions lasting for a month. Her abdomen was enormously distended, especially in the upper portion. It was rather symmetrical, dull on percussion all over the anterior and lateral portion, except in the lumbar regions, where slight resonance was observed. There was fluctuation in the lower part, but in the upper portion it was very obscure. The skin on the lower surface of the abdomen was in a condition of elephantiasis.

Vaginal examination revealed the uterus slightly retroverted, rather mobile, and gave a sound-measurement of three inches. The lower surface of the tumor could just be felt by the vaginal examination. The patient had a very weak pulse, indeed it could not be felt at all at the left wrist, and she had great dyspnœa on the slightest exertion.

Operation was performed on August 2. I was assisted by Drs. J. C. Bowen, G. H. Franklin, J. A. Clark and H. C. Bloom. An incision three inches in length was made in the usual position. The skin at the point of the incision was fully half an inch thick and very vascular, and considerable subcutaneous adipose tissue was present. As soon as the tumor was reached it presented the appearance common to ovarian growths, but it was found to be closely adherent to the abdominal wall. After separating as far as the finger would reach, the tumor was punctured with Tait's large trocar, and about four gallons of greenish fluid drained away; but only the lower portion of the tumor collapsed, the greater and upper portion remained as before. This was punctured in a number of places without removing the instrument from the cavity which had been drained, but nothing followed. The opening in the tumor was now enlarged and the hand introduced; the multilocular condition was broken down, large pieces of semi-solid substance being torn loose from the cavity of the tumor and brought away, together with a great deal of semi-fluid *débris*. As soon as room was gained, the hand was carried outside the tumor, when it was found to be adherent to the liver, stomach and everything with which it came in contact. These adhesions were carefully separated and after considerable effort the remainder of the tumor was finally brought out through the incision, which had been previously increased to 3½ inches. The pedicle, which was found to be thick and quite vascular, was transfixed and ligated, and the tumor cut away. The cavity was irrigated with filtered, boiled water, as much as two gallons being used. The irrigating tube was carried in every direction until the water returned clear. The right ovary was not removed, it being in apparent health. The wound was closed around a drainage-tube. There was considerable shock. The pulse could not be felt at either wrist, and it was two days before it returned, although the patient seemed to be doing well. The usual after-treatment was carried out, and the patient has made an excellent recovery. She went home (two hundred and fifty miles) on the 27th day, and still remains in good health. The temperature never rose above 100°; the drainage-tube was removed on the second day. The tumor was a multilocular cyst and weighed about 90 pounds.

On September 5 I was asked by my friend Dr. R. Armstrong, of Lock Haven, to meet him in consultation over a patient with abdominal tumor, who, he stated, was in such extreme condition that he feared she might not live until my arrival. I saw the patient on September 6. She is 21 years old, and single; puberty had occurred at twelve, and menstruation had always been profuse, coming on every three weeks and always being attended with some pain; she did not consider this abnormal, and so far as she knew was perfectly well up to four months before the above date. In the latter part of April of this year, after unusual exertion about the house, she was suddenly attacked with severe cramp-like pain in the right iliac region, so severe indeed the neighbors were alarmed by her outcries. This attack occurred about the time of her expected menstruation, and continued until the flow followed, when she

gained considerable relief. But she remained ill from that time; she was able to go about, however, in the intervals between the series of attacks of pain of similar character which now followed. Within two weeks after the first attack she noticed that her abdomen was increasing in size in the painful region, and from that time to the time of my visit, just four months, her abdomen had grown to an enormous size. I found her occupying a semi-recumbent posture, and breathing with difficulty. She was emaciated to such a degree, and the tumor was of such size, that she was almost hidden from view beneath it. The surface of the abdomen was purple from interference with the capillary circulation, and the veins were greatly distended. The abdomen was symmetrical and smooth. Fluctuation was rather obscure. There was dulness on percussion all over the anterior and lateral surfaces of the tumor, except at a point far back in the left lumbar region, where slight resonance was found. On the upper right border of the tumor, in the region of the liver, there was an apparently solid mass, shaped somewhat like the liver, suggesting the possibility that the cyst had grown from that organ. This was given more prominence on account of the rapidity of the growth. The patient was unable to retain anything on her stomach, and she had not slept, except at short intervals, for weeks. Her bowels were constipated and the urine was passed frequently and in small quantities. Her pulse was 140 and very feeble. Her expression was an appealing one, and she begged to be relieved.

A tablespoonful of whiskey was given and repeated in two hours, just before the administration of the anæsthetic. I was ably assisted in the operation by Drs. Armstrong, Ball and Watson, of Lock Haven. An incision two inches in length was made. The surface of the cyst was adherent to the peritoneum. After separating the adhesions as far as I could I plunged a large trocar into the tumor. But the contents were semi-solid. I therefore cut through the cyst wall and proceeded to break up and remove the contents. The cyst was adherent to everything it touched—liver, stomach, and other viscera; but the adhesions were weak and in ten minutes' time the tumor was removed, and the pedicle, which was thick and vascular, was ligated. The omentum was so firmly adherent to the cyst that it was ligated and amputated. The friable cyst wall was ruptured in many places and a great deal of the viscid semi-fluid material escaped into the abdominal cavity, but I did not lose time in trying to prevent this. When the tumor was removed what was left of the patient was an exceedingly small portion. The emaciated abdominal walls lay close to the spinal column and sunk into the pelvis. She looked more literally "nothing but skin and bones" than anything I had ever seen before. The abdominal cavity was thoroughly washed out by irrigation through a fountain syringe, and I was careful to pass the nozzle high up among the intestines and under the surface of the liver and diaphragm. The water returned clear and the incision was closed around a drainage-tube, and the patient returned to bed with a better condition of pulse and appearance than she had had before the operation. She did not show any evidence of shock and was conscious almost as soon as she was placed in bed. Her body was so emaciated that it was necessary to pack with cotton about the pelvis and along the spinal column, as the bones almost projected through the skin, and at several places bed-sores were apparent. The right ovary seemed smaller even than its natural size and appeared healthy; it was therefore not removed. The after history of the case has been without event. Her temperature never rose above 100°; it was normal on the third day after the operation. The pulse gradually diminished from 140, and was normal on the fifth day. The drainage-tube was removed within thirty-six hours after the operation. The sutures were removed on the eighth day, when union was found complete, except at the lower portion where the drainage-tube had been, and this has since healed. She began taking solid food on the third day, and on the fourth day her bowels were moved. The tumor weighed about 75 pounds.

The points of considerable interest in these cases are the location, character, and severity of the early symptoms, as well as the location of the tumor when first noticed (on the right side), while the tumors were of the left ovary, the right being perfectly healthy; the large size and very rapid growth of the tumors; the rapid recovery of the patients although in extreme condition, especially in the case last mentioned; the fact that the two cases are alike in nearly all particulars, the only difference being that in the second case the rapidity of the development was much greater, and the severity of the symptoms likewise greater; and lastly the method of removal of the tumor, that is, the breaking up of the semi-solid contents with the hand, thereby permitting their removal through a very short incision. I wish here

especially to call attention to a fatal case which occurred in my practice several months ago, and which forcibly illustrates that there may be danger in introducing the hand for the purpose of breaking down contents of the tumor, not knowing exactly the location of the intestines. In the case referred to, the friable wall of the main cyst had ruptured and some coils of intestine were found to be in the cavity and closely adherent to the more solid portion of the contents. Very careful manipulation was necessary to separate the bowel, which was finally done after considerable time had been spent in the effort. Ordinarily, however, where the cyst has not previously ruptured, the procedure is a safe one when due care is observed.

Dr. M. Price reported a case of

Pyosalpinx with Rupture.

On the sixth of September I was called to Mrs. ——, who had symptoms of miscarriage, with pains, hemorrhage and slight odor to the discharge. She refused to permit an examination, saying she knew she was not pregnant. I left her with the injunction that when she was ready for me to examine her to send for me. On September 10, I was again called, and found her in great pain; the discharge of blood and broken down placenta was of the most offensive character. She stated that she had been perfectly regular up to her last period, which was delayed about one week. She had considerable fever, a temperature of 102°, and had had that morning a severe chill. On examination the uterus was found about four inches in depth, with part of a rotten placenta adherent to its right posterior wall. The uterus was in good position and perfectly movable, with both tubes enlarged and thickened, and at this time could not have been adherent to any surrounding structures. I removed the placenta with considerable difficulty, used intra-uterine irrigation with hot water containing boric acid, which for a time gave her great relief. These irrigations were continued and the uterus washed out twice a day for three days; all this time the tubes continued to enlarge, until they must have contained several ounces of matter, but could have, at this time, been easily removed. The irrigations into the uterus were discontinued and those of the vagina were kept up. I became very much alarmed at her condition and stated to the husband that an operation was needed to save his wife's life. This he refused, and begged that I should do all I could without the operation. I yielded to his request much to my regret, for I felt that nothing but an immediate operation and removal of the tubes would save her life. I believe that any man, treating a case of this kind with the symptoms as positive and the indications for operation as plain as they were in this case, should retire from the case if an operation is refused, for by so doing he clearly indicates that his mind is made up as to the treatment, and by withdrawing shows to the medical attendant who may be called to the case the proper line of treatment; if the latter does not take the warning, the post-mortem will follow and show who was right. There were several well-marked changes in her condition indicating rupture or leakage from the tubal abscess, and her condition steadily grew worse until the 20th, when in consultation with my brother, we persuaded the family and the patient to let me operate and give her that chance for life, as she was in a very bad septic condition. As the consultation was at a very late hour at night, she was opened early the next morning, Sept. 21. I found the internal organs matted together, uterus much enlarged, both tubes enlarged and ruptured, adherent to everything they touched, pelvis full of pus cavities, pus cavities almost up to the kidneys on both sides; everything was in a semi-gangrenous condition. There was little bleeding from ruptured adhesions or from the wound made in opening the abdomen, which is never a good indication. A great quantity of pus was evacuated, at least two pints; it was of the most offensive character. Irrigation and drainage were used. The patient was a very large woman, consequently the longest drainage-tube we could find was used. She rallied from the ether and for the first six hours there were discharged from the drainage-tube two pints of very offensive serum. It gradually lessened in quantity but increased in offensive character. A cleaning of the tube was made every half-hour; after cleaning, warm boracic water was injected through the tube. It improved matters only for the moment. The patient died twelve hours after the operation. Present at the operation: Drs. Joseph Price; E. W. Cushing, of Boston; Atherton, Toronto; Roseburg, Hamilton, Ontario.

Dr. W. H. Parish said that his remarks on this subject of pelvic abscess made at the recent meeting of the American Gynæcological Society had been misquoted. He had stated there, and wished to repeat here,

that these abscesses should be opened very early. If operation were not resorted to, the patient would most probably either die or become a confirmed invalid. He was not one of those who believe that pus always originates in one particular point in the pelvis. He did, however, believe that the large majority of cases occur because of pus primarily in the tube. He believed also that an uncertain number occur from pus originally formed in the areolar tissue, beginning probably because of lymphangitis of that particular locality. The question arises, how best to operate in these cases. He held that there could be no absolute rule of procedure. He believed that in the majority of cases it is wiser to make an opening in the median line and explore the peritoneal cavity, unless we are very certain that the abscess is not in the tube or ovary. If we are sure that there is no involvement of the appendages and that the pus is not intra-peritoneal, the abscess may be opened without going into the cavity. He called attention to a procedure he had adopted in a few instances, where small abscesses were located in pelvic areolar tissue. In one instance Dr. Longaker made an incision in the median line. The tubes and ovaries were found free from pus, but of course congested. With the fingers within the abdomen he felt an abscess in the anterior pelvic wall. An incision was made over Poupart's ligament, as for ligature of the external iliac. Then passing deep into the pelvis, pus was reached some distance below the brim of the pelvis. In another case there was an indurated mass apparent above the left half of the pelvis, not recognizable through the vagina, except on very deep pressure. An incision was made above Poupart's ligament. After cutting through very dense tissue, he came to a minute cavity, which contained no pus, but a somewhat serous fluid containing flakes of lymph. These are only two of a considerable number of pelvic abscesses on which he had operated, and he had never regretted operating early.

Dr. J. M. Baldy wished to take this opportunity of emphasizing views which he had expressed before the recent meeting of the American Gynæcological Society. He did not agree with Dr. Parish as to the pathology of this affection. He granted that there was the possibility of an abscess occurring in the pelvis, such as occurs in other parts of the body from the scalp to the foot, but held that these must be most rare. The gentlemen connected with what Dr. Parvin had been pleased to call "the Philadelphia Dispensary School of Surgery," had now done over one hundred of these operations, and had not yet in a single case come across one which had not begun primarily in the tubes or ovaries. In every case the diseased mass removed has been tube, ovary and other tissues involved. (Dr. Parish, at this point, asked wherein his views differed from those of Dr. Baldy. Dr. Baldy said he would have to leave that to be judged from what Dr. Parish had said.) In regard to treatment he must again dissent from the views expressed. He thought that an absolute rule *could* be laid down. Where pus was found in the pelvis, early or late, the proper procedure was to open the abdominal cavity and remove the seat of the disease, where it was possible; and where it was not possible to remove, proper drainage should be established. However, it would be found comparatively seldom that the disease could not be taken out by a bold operator.

Dr. Joseph Price thought that he understood Dr. Parish. He himself had said repeatedly that we might have an abscess in any part of the body from the scalp to the matrix of the nails; we may have it in the cellular tissue of the pelvis as well as in the axilla or neck; but he must hold to what he had said, that in all the pelvic abscesses that he had seen he had not found one not due primarily to tubal disease. Among the recent papers on the subject, one calls attention to the treatment by drainage through the vagina. He did not see how this would avail much in bilateral accumulations. Half of the tube may be evacuated, but a condition of affairs is left such as is found in an old bubo. In pelvic abscess we have just the condition of affairs which the surgeon is asked to treat in the groin, axilla or popliteal space. In such a case he would remove the disease by a clean enucleation and perfect a cure. He had not seen a case of pelvic abscess which could not be removed in this way, and he should say that such cases did not exist. One gentleman at Washington went so far as to say that after drainage by the vagina in a case of double pyosalpinx, recovery had followed—the woman had borne children. He might as well have said she had conceived, notwithstanding her husband had previously been castrated.

Dr. M. Price remarked that it was doubtful if disease of the tube could be determined by simply looking at it. He remembered a case a few weeks ago, in which the

tube was congested and inflamed. It seemed to be simply swollen, but on pressure there was forced from the fimbriated end a drop or two of as perfect gonorrhœal pus as could be found anywhere. If he had not seen the discharge, he should have thought that there was no disease save congestion.

Dr. W. J. Taylor presented with the following remarks:

Three Uterine Myomata.

These three tumors were removed to-day from a case of considerable interest. The patient, a woman 30 years old, was married on 7th of last May. On the 20th she had her last menstruation and from that time considered herself pregnant. The abdomen began to swell, and she had a good deal of pain. A few days ago she sent for me and I found her with the abdomen much enlarged and presenting the symptoms of pregnancy. On the right side, however, there was a hard mass which puzzled me very much. She was seen by Drs. W. W. Keen and B. C. Hirst and the conclusion was reached that an operation was necessary. To-day abdominal section was made. It was found that the uterus contained a fœtus, and that there were three fibroid tumors: the largest was sub-peritoneal, the smallest was attached by a small pedicle, and the second in size was also sub-peritoneal. These were removed and the patient is at present doing well.

Dr. W. W. Keen said that Dr. Taylor had hardly done himself justice in his modest narration of the steps of the operation and in his reference to the question of diagnosis. "When I saw the patient last Monday it was a question whether the large mass on the right side was a uterine myoma or a tubal pregnancy. It had grown rapidly and *pari passu* with the uterus. Two facts in favor of its being a solid tumor were its density and the fact that the pulsation of the aorta could be distinctly heard with the stethoscope at every point over the tumor. Its rapid growth seemed to be opposed to the idea of myoma. Dr. Hirst was of the opinion that it was a tubal pregnancy, at the same time recognizing an intra-uterine fœtus also. She had albuminuria. When Dr. Taylor opened the abdomen two large tumors presented, which coalesced below but were separated above. Passing the hand into the abdomen the left tube and ovary were found normal. On the right side, it was at first not possible to recognize the ovary and tube, but by enlarging the incision the hand was passed well down and the ovary and tube found. By the side of this tube was a vein considerably larger than my thumb. The pregnant uterus was recognized as the large tumor to the left. It was soft, elastic and dark in color. That to the right was recognized as a neoplasm. While I lifted with difficulty the upper end of the tumor, Dr. Taylor incised its capsule and enucleated it until he came to the attachment to the uterus, which was over a space of three or four inches in diameter, when the weight of the tumor then caused the uterine tissue to tear and the large sinuses began to bleed very freely. I next grasped the pedicle with the thumbs and forefingers of both hands while he stripped off the sac. The tumor was thus quickly removed and the uterine tissue and the wall of the sac were seized with large hæmostatic forceps and the hemorrhage controlled. It was necessary at several points to introduce sutures into the uterine wall itself to control the bleeding. The redundant portion of the sac of the tumor was cut away and the edges brought together with the continuous cat-gut suture. A drainage-tube was passed down into its cavity. In at least two places and possibly four, there were upon the uterine wall small masses about half the size of my little finger nail. These looked like beginning malignant tumors. From the appearance and the rapidity of the growth, I think that this may be a sarcomatous tumor, though it is possibly a simple myoma."

Dr. Parvin thought that there was one point that even Dr. Keen had omitted. He saw the operation and the great mass of the tumor was included between the layers of the right broad ligament, so that the first incision was through the anterior layer of the ligament. Formerly, in removing a sub-peritoneal fibroid from the posterior surface of the uterus, the pedicle partly tore while the ligature was being applied, and there was free hemorrhage. He finally succeeded in stopping the bleeding by the use of the continuous cat-gut suture, after other measures had failed.

Dr. Hirst said that Dr. Keen had correctly expressed his views. The symptoms pointed strongly to extra-uterine pregnancy. If the case had been allowed to go on to term, Cæsarean section would have been required, as the tumor filled up the pelvis. He had looked up this subject of injuries to the pregnant uterus and had found some interesting cases. In one case the woman was thrown to the ground and jumped upon when six months pregnant. The fœtus was

killed but she went on to term. In another case trachelorrhaphy was performed during the second month of pregnancy. This case went on to term. In another instance a number of leeches were applied to the cervix of a pregnant uterus without any interruption to pregnancy. "In a case I had last spring, the woman was squeezed between a bale of goods and the wall and was seriously injured, but she went on to term. A German operator has such confidence in his ability to plunge a trocar into the uterus without doing harm that he advocates the occasional withdrawal by aspiration of the liquid in hydramnios with very great distension of the uterus, allowing the child to go on to term."

Dr. Parish said that the removal of ovarian tumors during pregnancy was recognized as a proper operation, but that the removal of uterine sub-peritoneal fibroid tumors during pregnancy was not regarded as a proper operation except under certain special circumstances. The injury necessarily inflicted on the uterus in their removal is liable to induce abortion. It would be interesting to have the further history of this case. The microscope alone could determine the character of this growth. Under ordinary circumstances the rapidity of the growth would point to sarcoma; but it is well known that in pregnancy fibroid tumors occasionally take on a rapid growth. He supposed that Dr. Hirst did not refer to the cases he had cited as indicating rules of practice. It must be the urgency of the condition which justifies operations on the pregnant uterus. While pregnancy may go on after injuries to the uterus there are numerous unreported cases in which the opposite has been the result. Where a sub-peritoneal tumor can be lifted from the pelvis, pregnancy may go on.

Dr. J. Price thought that obstetrically the case was one of great importance. Some time ago he had called attention to three parallel cases. They all went to term with a pelvic tumor and died undelivered. The question of differential diagnosis scarcely concerned many operators at present; all that was required was the knowledge that there was a tumor present. We should never wait until the patient's general health has been impaired, as this is a departure from that generally followed in general surgery.

Dr. Hoffman had been recently consulted by a woman who stated that she was pregnant and that at previous labors the baby "had to be mashed up." The pelvic cavity was found to be filled with a tumor. She was advised to undergo an operation for its removal, but she refused. It seemed to him that there could be no doubt of the propriety of immediate operation in cases like the one before him.

Dr. B F. Baer believed that, in this case, after the exploratory incision had been made and it was found that no extra-uterine pregnancy existed, it would have been better to have closed the incision than to have removed the deeply located solid tumor; but since the removal was determined upon, he thought it would have been better to have amputated the uterus at the neck, than to have permitted it to remain with a great wound in its side and in the broad ligament. It is not likely that after such a serious operation the pregnancy will go on to term anyway, and abortion occurring within a short time after the operation will certainly add to the risks of the patient. He asked if there were any subjective signs of pregnancy (extra-uterine) in this case, such as the peculiar pains, uterine hemorrhage or discharge of decidua?

Dr. Keen thought that the removal of the uterus would have been a wholly unjustifiable procedure. It was possible that the woman might miscarry, but it was also possible that she would go to term. It has been shown that pregnancy is not necessarily a bar to operation. Not only would the sacrifice of the fœtus have been unjustifiable, but hysterectomy would have made a young married woman sterile. The added dangers of a hysterectomy too might have turned the scale against the patient.

Dr. B. F. Baer said that in regard to the removal of the uterus in this case, it seemed that Dr. Keen condemned the procedure because of his anxiety to save the child. He, however, believed that the child would have had a better chance for its life if nothing had been done. But if operative measures were imperative, then he still held to his former opinion. In answer to a question from Dr. M. Price, he said that he believed that hemorrhage may occur and the extra-uterine sac remain unruptured. He had seen a case which supported that view. The patient after missing her menses for two months, was one day seized with severe pain in the right iliac region, which was followed by shock. She fell in her yard, and when her physician arrived he found a condition of shock as well as hemorrhage. A few weeks after, she had a similar attack. He was then sent for and the diagnosis of extra-uterine pregnancy arrived at. This was five years ago, and Thomas's

method of operating by the vagina and opening the sac was followed. The sac was found with no evidence of rupture in it. The liquor amnii was clear and no evidence of hemorrhage into the cyst, which there would have been had a rupture taken place. The fœtus was, indeed, alive. The patient died on the fifth day after operation.

Dr. Wm. J. Taylor closed the discussion by saying that in this case the tumor was absolutely fixed. The woman's general condition was poor; the pulse 120; the patient unable to eat; she suffered intense pain and diarrhœa for a number of days before the operation. The tumor was also growing rapidly. The urgency of the case seemed to call for some relief. There was albuminuria. If the mother had been allowed to go on to term—provided the woman had lived that long—the risks to both mother and child would have been greater than they are at the present time.

Foreign Correspondence.

LETTER FROM COLOGNE.

(FROM OUR SPECIAL CORRESPONDENT.)

The present century, which has often been named the era of inventions, might with equal propriety be termed the era of exhibitions and conventions. This would be especially true of Germany, for no people in the world exhibit a greater fondness for meetings, social or scientific, than do Germans. The medical profession in Germany has long recognized the great practical advantages and scientific value of frequent and unrestrained meetings. The annual convention of German physicians and naturalists, enjoying by special invitation the hospitality of a different city every year, is justly regarded as one of the most important meetings of German physicians. This year Cologne had the distinction of gathering within its ancient walls eminent medical men from near and far. At this meeting there were present Virchow, the pathologist, archæologist, and politician; Waldeyer, the foremost of German anatomists; Bardenheuer, Binswanger, Lassar, Weissmann, Meynert and a host of other physicians, many of whom are well known in America. Your correspondent counted the number of physicians present at over 800.

Binswanger, of Jena, read an admirable essay on *Crime and Mental Disorders*. The notions of good or bad, of health or disease, the speaker said, are not absolute and cannot be divided by distinct lines of demarcation. The duty of a judge to test carefully the degree of the psychical liberty of a defendant becomes more and more evident. There are doubtless in our prisons persons with imperfectly developed mental capacities, in whom various inhibitory functions are disordered. There exists no doubt an innate and inherited moral defect which, with inexorable necessity, leads to crime. Judge and physician will readily agree in their decision where pronounced lunatic features are manifested by a criminal. But the distinction between a criminal lunatic and a demented criminal is often as difficult as it is important to make. Above all, we have to distinguish between the *occasional* and the *habitual* criminal, for the former is not subject to a permanent inhibitory influence of his mental powers. In this respect it will be necessary to examine in each instance the individual psychical development; in other words, to elucidate the biology of the criminal. There are psychiatrical observers, such as Lombroso and Benedict, who believe that criminal tendencies are present in all persons, and that crime has a direct relation to the development of the brain and skull. But Binswanger emphatically repudiates such views, and ridicules both Lombroso's "criminal skull" and Benedict's "confluent criminal brain." A single symptom is, to the rational physician, never indicative of a certain affection, as it may be produced by various causes.

Virchow's lecture on *Artificial Deformities of the Body* was listened to with unusual interest. He thundered against the baneful influences exerted on the human body by various modern fashions. What is the use, Virchow asked, of introducing the principles and appliances of hygiene into the huts of the poor and ignorant, when the scions of wealth, pretended intelligence, and fashion, especially in the gentler sex, show their contempt of hygiene by their dress and general wearing apparel? In days gone by, the speaker said, I have battled against the diabolical invention called the corset; but this crusade has been given up by me as absolutely futile. The French shoe, with pointed toe and the heel under the middle of the foot, is another fashion which, on account of its detrimental influences on the body, cannot be opposed too energetically. Even the modern stocking, pointed and symmetrical, is injurious to health, as it does not conform to the anatomical formation of the foot. Virchow believes that the modern shoe and stocking, by weakening the toes, invite gouty deposits.

Waldeyer spoke upon *Women and the Study of Medicine.* He objected to the admission of women to the medical profession, and supported his objection by arguments which, however, though skillfully presented, can not all be regarded as sound. A woman, Waldeyer said, is a receptive and not a productive being. The ranks of medical practitioners, however, should consist solely of physicians who are individually able to further the interests and the development of the healing art. A woman cannot produce, and is also deficient in the art of combination. Her sphere is well defined by nature, and only by confining herself to the same may she hope to fulfill her mission and tasks. Experience has proved, he said, that a female medical student, though conscientious and diligent, is, in certain branches, distinctly awkward. In the chemical laboratory she is neither tidy (?) nor sharp, and greatly inconveniences the assistants by perpetual and unnecessary questions. An American woman physician has recently written a book, he said, but, as was to be expected of a woman, the production was a weak one (*sic*). Waldeyer eulogized the great tact and invaluable services of women nurses, but thought that the gentler sex should be admitted to the ranks of practitioners only in exceptional cases.

The exhibition connected with the meeting also presented many features of interest. Special mention should be made of a new inhaler constructed by Jahr, of the Imperial Health Board of Berlin. The advantages of this apparatus are: (1) it secures a more accurate dosage of medicines than has been hitherto feasible; (2) it prevents the condensation of too great quantities of the medicine in the mouth and throat; (3) it insures a longer and more energetic action of the medicine on the upper air-passages. The principle of the apparatus is based on the fact that medicine suspended in vapor which is of a higher temperature than the body is precipitated upon coming in contact with the respiratory passages, on account of the cooling of the vapor which then occurs. Another exhibit of interest was an aseptic pair of scissors. The peculiarity of the scissors consists in the absence of the joint, the scissors consisting of two blades which at the time of being used are easily joined like the two blades of a pair of forceps. The absence of the joint permits complete asepsis of the scissors.

Cologne,
Sept. 30, 1888.

PERISCOPE.

Diuretic Property of Preparations of Mercury.

The diuretic effect of the preparations of mercury has received thorough study from Dr. Wladyslaw Bieganski, who communicates a paper on the subject to the *Deutsches Archiv für klinische Medicin,* September, 1888. After referring to a previous paper by Dr. Jendrássik, whose results unfortunately remained inconclusive, he proceeds to give the results obtained in his own cases. The clinical value of the reports of his cases is much increased by the tables, which give the daily record of the medicine taken, the quantity of urine passed, its specific gravity, and remarks upon the condition of the patient resulting from the administration of the calomel. His first patient was a man 54 years old, who 25 years before had had syphilis. In the winter of 1885, he first noticed that his feet were swollen. After trying many domestic remedies in vain, he entered the hospital in August, 1886. It was there found that he had insufficiency of the tricuspid and of the aortic valves, with hypertrophy of the left and dilatation of the right heart. Both pleural cavities contained fluid, the exudate extending up to the eighth rib behind and to the fifth rib in front. There was also ascites and great œdema of the lower extremities. All the visible arteries were hard and tortuous, and the liver was enlarged and hard. Under treatment with calomel, in doses of forty-five grains a day, when necessary given with opium to prevent diarrhœa, the quantity of urine increased, the dyspnœa and œdema diminished, the latter disappearing entirely under the continued use of calomel. When the calomel was stopped, however, the symptoms reappeared, showing that the action of the drug was only temporary.

The second patient was also a man, and 67 years old, and affected for a long time with chronic bronchitis and emphysema of the lungs; he also had dilatation of the right ventricle, œdema, and ascites. Calomel was given as in the previous case, and the œdema disappeared, though more slowly than in the first case.

In the third case, a man 55 years old had chronic bronchitis with emphysema; dilatation of the right ventricle, consecutive insufficiency of the tricuspid valve; œdema and ascites. In this case the calomel failed to induce diuresis. The patient died, and at the autopsy amyloid degeneration of the kidneys was found.

The fourth patient was a young man 30 years old, who was known to have nephritis. There was marked œdema of the lower extremities, ascites, and a feeling of weakness. Calomel was given as in the other cases, but death resulted. No diuresis occurred, but rather a diminution in the quantity of the urine.

Bieganski devotes some time to determining the mode of action of calomel. At the outset he disputes the theory of Jendrássik, who maintained that calomel is absorbed into the blood as an albuminate and leads to a greater sucking up of fluids from the tissues, the fluids being immediately excreted by the kidneys. According to this view, the action of calomel would be like that of the diuretic salines. To determine the mode of action of calomel, Bieganski instituted experiments upon healthy people, employing in two cases calomel; in four inunctions of mercury, sometimes after calomel had been given and stopped, and sometimes from the first; in one case pills of corrosive sublimate, and in three cases injections of mercury, either of the black oxide or of corrosive sublimate.

His general conclusions are: 1. Calomel and other preparations of mercury act as diuretics, the quantity of urine excreted being at times very considerably increased. 2. For a few days after any of the mercurial preparations are given a diminution in the quantity of urine excreted generally occurs; this gives place to diuresis from the second to the tenth day. 3. The diuretic action is manifested best in œdema the result of heart failure. Pathological changes in the kidneys limit or entirely abolish the diuretic action. 4. Diuresis occurs just the same, whatever preparation of mercury and whichever method of prescribing is employed; but it is most marked after hypodermic injection, less after internal administration, and least after inunction. 5. The amount of the preparation is of most importance; small doses are not diuretic, this action being peculiar to moderate-sized and larger doses. 6. The quantity of urine excreted fluctuates, and these fluctuations may amount to twenty-four or thirty-six fluid ounces. The diminution and increase occur pretty uniformly every two days. 7. The diuretic action of mercury depends probably upon the irritation which the mercury during its excretion exercises upon the kidney substance.

In the same number of the *Deutsches Archiv*, Dr. R. Stintzing communicates a paper on clinical observations upon calomel as a diuretic and hydragogue, from Von Ziemssen's clinic. He experimented with calomel upon twenty-seven patients with different affections, and concludes that it is the most energetic of all diuretics. It acts best, he says, in cardiac dropsy, either as the result of valvular lesions or of affections of the heart muscle. This action fails or is unsatisfactory if the insufficiency of the heart has reached the highest degree; but in that case other agents also are ineffective. In dropsy of other causes the calomel treatment is less applicable. In heart disease combined with chronic nephritis, calomel still comes into play if the nephritis is in the background as regards the heart disease. In the obviating of cardiac dropsy with calomel not only the increased diuresis but also the watery stools play an essential *rôle* The freer the elimination by the former passage the greater the general result. Accompanying effects of the drug—salivation, stomatitis, diarrhœa, colic, etc.—may be checked by appropriate prophylaxis, or kept from doing injury in all cases in which polyuria is obtained. If the diuretic action does not occur, then symptoms of mercurial poisoning always occur. The best dose is that proposed by Jendrássik, three grains three times a day. The administration of it must be continued at least three days, but in special instances may be kept up with good result for twelve days. If the dropsy does not completely disappear, or if it returns, the calomel is to be repeated. Gargles of chlorate of potash should be used from the beginning as a prophylactic against mercurial stomatitis; and the calomel should be combined with opium. One-third of a grain of opium is sufficient generally for three grains of calomel. If stomatitis or severe and persistent diarrhœa occur, the calomel is to be stopped at once. The quantity of urine begins to increase generally from the second or fourth day, rarely on the first or fifth day of the administration of the drug. Polyuria lasts in successful cases at least three days, generally four or five, in rare cases more, up to twelve days. The greatest quantity of urine passed in any of his cases was 8350 cubic centimetres (about nine quarts). Digitalis and other diuretics act as diuretics less powerfully than calomel; but calomel cannot substitute them, for it is no cardiant.

—In the *Lancet*, October 13, 1888, Mr. Frederick Treves reports a case of intestinal obstruction due to a very rare cause—hernia into the foramen of Winslow.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

RECOVERY FROM HYDROPHOBIA.

A pleasing variation from the usual reports of cases of hydrophobia comes, under date of September 24, from St. Louis. According to the newspaper reports, a boy, fourteen years old, had developed what are often considered to be the symptoms of hydrophobia. He is said to have barked and frothed at the mouth, and to have gnawed at the carpets and chairs. Physicians being summoned to his assistance, it is said that they confirmed the popular diagnosis of hydrophobia, and instituted the customary plan of treatment, the boy being held by strong men and fastened to his bed, and the usual prognosis of death being given. In this case, however, fortunately for the lad, he disappointed the expectations of those who watched over him, and after a short period of unconsciousness, during which he was probably free from the kindly but unwise ministrations to which he had been previously subjected, he revived, and manifested no further symptoms of this dread disorder.

The evidence that this boy had genuine hydrophobia is not to be dismissed as entirely unworthy of belief; for the reason that it is quite as complete and quite as well authenticated as in the great majority of cases in which death follows instead of recovery. It is true the amount of evidence is not very great to the scientific mind, but it would be sufficient, we think, to convince Monsieur Pasteur, if we are to judge by the history of some of the cases to which he has applied his method of preventive inoculations.

The most suggestive part of this story, in our opinion, is that which states that the boy's recovery followed promptly upon the period in which he was not subject to any medicinal or mechanical treatment. And, to be entirely serious, we believe that this, which is in accord with some of the most scientific observations on the treatment of tetanus in horses, indicates in the present state of knowledge—as opposed to prejudice—in regard to hydrophobia, a part of the treatment which, whatever else may be done, is absolutely essential to the proper management of these trying and terrible cases.

THE ABUSE OF CHEMICAL ANALYSIS.

The rapid multiplication of real or pretended chemical analysts of late years, and the keen competition of manufacturers of pharmaceutical and food preparations, have brought about a state of affairs which may prove somewhat perplexing to the medical practitioner who desires to advise his patients intelligently in regard to their medicines, their foods—and, perhaps, their drinks. It has become the fashion to spread before him what purport to be exact statements as to the ingredients of various articles recommended to his notice—a fashion which is to be commended whenever it is honestly

followed, and which, under these circumstances, brings the manufacturer into the best possible relation to the practitioner of medicine. But, unfortunately, what might, if rightly used, be of the greatest service to physicians has proved so powerful an assistant to commercial ventures that it has come to be abused and prostituted to utterly unworthy purposes. Thus, the advertising pages of medical journals, and, in some regrettable cases, their reading pages, often present reports of so-called analyses which have been framed, not to instruct but to deceive those to whom they were addressed. On the other hand, honest and faithful analyses have been garbled, or parts of them have been picked out and used to advertise articles which the analysts themselves had no idea of recommending.

Examples of this practice have been furnished of late in different parts of the United States. In this city a well-known chemist has recently found it necessary to disclaim responsibility for the way in which his report as to the presence or absence of salicylic acid in certain specimens of beer has been used by the manufacturer of one of them as a certificate of its absolute purity. In other cities we have had flagrant examples of analyses which seemed to show that articles suspected or asserted to contain dangerous ingredients were free from them; and analytical testimonials to the worth of medical and sanitary preparations seem to have become in some places a regular article of commerce.

For these reasons chemical analyses have lost the credit which they once had, and which they ought to have, with physicians. But, besides this, they have proved injurious in some cases to the manufacturers themselves; for, with the advent of reports which misrepresented certain medicinal and food preparations in the interests of those who sold them, there have come reports which misrepresented them quite against these interests. A recent example of this is found in the history of a much-used food-preparation, the manufacturers of which have been prompted to collect and publish evidence to show that a chemist whose name is familiar to all readers of the advertisements in medical journals has made a report in regard to the ingredients of this food which is marked by prejudice or stupidity.

Some of this evidence has been published in certain medical journals which had before given publicity to the adverse report, and its absence from the columns of the REPORTER is due only to the fact that we have not admitted anything to them which seemed to bear plainly the mark of commercial controversy. The inflexible rule of the REPORTER is to restrict advertisers to the advertising pages; and, as we have steadily refused to publish in our reading pages laudatory notices of commercial articles, neither will we admit to them criticisms prompted solely by business competition. When actual fraud has been proved, or when it has been shown to be highly probable, we have not hesitated to express our opinion; but we have not taken part in controversies about commercial preparations for any less serious cause.

In regard to much that passes for chemical analysis we feel that our knowledge is not sufficient to enable us to give a judicial opinion; and, until we feel more confidence than we do now in our judgment on such matters, we must confine those who contest about them to our advertising pages, and restrict our own utterances to such general statements of principle as may aid the readers of the REPORTER in arriving at just conclusions.

At present our purpose is to call attention to the abuse of chemical analysis which is bringing discredit upon a method of advertisement which might be of the greatest service to our fellow-practitioners, and of the greatest advantage to honest manufacturers. The first step toward the correction of this abuse is to point it out; and we trust the succeeding steps will appear before long.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THEINE IN THE TREATMENT OF NEURALGIA. By Thomas J. Mays, M D., Professor of Diseases of the Chest in the Philadelphia Polyclinic, etc. 16mo, pp. 84. Philadelphia: P. Blakiston, Son & Co., 1888. Price, 50 cents.

This little book contains an essay on Theine already published in the *Polyclinic* during the latter part of 1887 and the beginning of 1888. Dr. Mays has made a very thorough study of this drug, both physiologically and therapeutically, and has demonstrated its value as a remedial agent in the treatment of various forms of neuralgia. It is our impression that the results of his study are not as well known as they ought to be, and we strongly recommend our readers to get a copy of this cheap and valuable monograph, and learn what theine actually is and what service it may render them in their practice.

CORRECTION.

By an error in the review of Dr. Howe's book on "Excessive Venery, Masturbation, and Continence" (Reporter, Sept. 29, p. 413), the publishers were stated to be J. H. Vail & Co., instead of E. B. Treat, New York.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

The Therapeutics of Diphtheria. By A. Jacobi, M D., New York. From the *Transactions of the Philadelphia County Medical Society*, May 23, 1888. 23 pages.

Conservatism in Gynæcology. By A. Reeves Jackson, M.D., Chicago, Ill. From the Chicago *Journal and Examiner*. 7 pages.

The Early Diagnosis of Spinal Caries, With Remarks on Treatment. By Hunter P. Cooper, M.D., Atlanta, Ga. From the *Atlanta Medical and Surgical Journal*. 10 pages.

The Treatment of Hemorrhoids. By Hunter P. Cooper, M.D., Atlanta, Ga. 9 pages.

Some Retrospective and Prospective Thoughts on Surgery. By Donald Maclean, M.D., Detroit, Mich. From the *Journal of the American Medical Association*, June 30, 1888. 33 pages.

Criminal Abortion, or Fœticide. By H. C. Ghent, M D , Belton, Texas. From the *Transactions of the Texas State Medical Association*, 1888. 28 pages.

Relation of Diseases of the Kidney, especially Bright's Disease, to Diseases of the Heart. By J. M. DaCosta, M.D., Philadelphia. From the *Medical News*, May 5, 1888. 37 pages.

—As the whole of Dr. Jacobi's paper was laid before the readers of the Reporter in our issues of June 23 and 30, 1888, it is not necessary to speak in detail of this reprint. But we can recommend its careful perusal to all who have not already read it in the pages of this journal, as the expression of the opinions of one who is justly celebrated for his study of this interesting subject.

—The substance of this pamphlet was published in the Reporter, June 9, 1888, in our report of the proceedings of the Illinois State Medical Society in May of this year. It contains a strong protest against the too frequent performance of abdominal section upon women, and denounces those whom the author suspects of operating more for their own glory than for the good of their patients, in most unqualified terms.

—Dr. Cooper's paper is chiefly devoted to emphasizing the importance of an early diagnosis of Pott's disease, and describing the way in which this diagnosis is to be made. This part of his paper is both interesting and instructive, while the part devoted to describing the treatment of caries of the spine is as brief as it is clear. Dr. Cooper recommends the use of the plaster-of-Paris jacket as "the easiest, cheapest and best treatment in the vast majority of cases."

—In this paper, which was read before the Medical Association of Georgia, April, 1888, Dr. Cooper very sensibly remarks that "a surgeon in general practice will obtain far better results if he thoroughly familiarizes himself with the details of two or three operations than he will by attempting to perform all of the dozen or more which have been recommended." His pamphlet contains a brief and succinct account of the different varieties of hemorrhoids, and describes three methods of operating for their relief: dilatation of the anus, injection of carbolic acid, and the ligature. The opinions of Dr. Cooper are the more interesting, in that his experience leads him to dissent from some of the views expressed by other surgeons. His paper is so instructive that it may well be recommended to the attention of our readers.

—Among the interesting features of Dr. Maclean's address before the Surgical Section, at the last meeting of the American Medical Association, is his defense of chloroform as an anæsthetic, which he has employed for thirty years, without an accident which could in any way be attributed to its use. His whole address covers a number of points of great importance in the practice of surgery, and is of the greatest value as expressing the mature opinions of a surgeon of unusual skill and judgment.

—Dr. Ghent has taken the pains to collect the opinions of a number of well-known medical men in regard to the frequency of criminal abortion in the United States, its causes, and the means for its prevention. To these are added, in the pamphlet before us, his own views as to the enormity of this crime and the duty of the medical profession in regard to it. As might be expected, he lays the greatest stress upon the right of the fœtus to life and care, and urges his professional brethren to use their best endeavors to promote correct views in regard to this matter among the persons who come under their influence.

—Dr. DaCosta's Middleton Goldsmith Lecture, delivered before the New York Pathological Society, April 18, 1888, contains a learned defense of his opinion that the "cardiac hypertrophy which is found in Bright's disease is not in any sense the consequence of that disease," and that it is in the nervous system that we must search for the original source of the malady, which includes both heart and kidney in its ravages. The vast experience and careful investigations of Dr. DaCosta lend great weight to anything he says, and his views on the important subject discussed in this address deserve the most careful attention of all pathologists and practising physicians.

CORRESPONDENCE.

A Statement from Dr. Willard H. Morse.

TO THE EDITOR.

Sir: I ask the favor of being permitted to answer with my side of the story, the editorial which appeared in your last issue concerning myself.

Although I am but a young country physician, in indifferent health, and without the facilities at the hands of many others, I have, during the eight years since my graduation from the Albany Medical College, engaged more or less largely in the study of new remedies, and in practical chemical work. It is true that instead of a large botanical garden, I have only a little plot of land, and instead of an extensive laboratory, only an office room with the necessary working apparatus. But I have worked as I could, writing the treatise "*New Therapeutical Agents*" (1882), and some sixty papers for the medical press. I do not boast of this, or of chemical labors, as what I have done speaks for itself.

You will remember that in the REPORTER for Nov. 26, 1887, I had a paper on "Gleditschine," which I think had a little to do with the exposure of that "alkaloid." At least it brought me a deal of prestige; and last spring, in looking for another like "foe to conquer," I had my attention attracted to the Scotch Oats Essence, which the *Druggists Circular* and Boston *Journal of Health* had stated to be base with opium and alcohol. It occurred to me that it would be a good idea to analyze the preparation and expose its character a little more fully than had been done. But on examining the bottle obtained for the purpose, I was surprised to find that it did not contain opium, although there was some alcohol present. I thought this strange, and proceeded to investigate the source of the charge. Finding the *Journal of Health* to be anonymously edited, and with its "chemist" acting under an assumed name, I concluded that the source was hardly creditable, and stated my findings (May 1). Soon after, I was advised by Dr. R. G. Eccles, now president of the State Pharmaceutical Society, and others, that I must have examined a bottle put out since April 18, since which time it was alleged that the preparation had been changed in quality, and the opium left out. This fact was not known to me, and I took immediate opportunity to purchase bottles of both the "guaranteed" and "non-guaranteed" articles, and to conduct a careful examination of both, according to advice of Dr. Eccles, and by a method of his prescription. The result was that I found that it was the "guaranteed" article which I had first examined. On May 31, I wrote Dr. Eccles as follows:

"*The results in corroboration show that the bottle first examined must have been one bearing the forfeit label.*"

Shortly afterward I wrote an article on the matter, but for reasons not deemed judicious, it was not published.

The *Druggists Circular* seems to have come to the conclusion—and a very natural one, too—that I was retained by, or interested in the Essence, in some way; and forthwith began its attack. On learning this, I addressed the editors the statement given above, and sent it to them through my pastor, Rev. J. A. Owen. To it I added—and I reiterate it now—that I have never met anyone connected with the manufacture of the preparation, and that my action was wholly voluntary, and uninfluenced by such parties. The outcome had meanwhile transpired.

The work done as a therapeutist had brought my name before the public, so that I have gradually come to do considerable work as a chemist. My reports I have sought to make thorough and careful; and to this end I have sent a copy to the manufacturer that he might suggest any corrections, other than chemical. As my reports are sometimes used for advertising purposes, it has been my custom sometimes to state that the copy can be retained for $10, if desired, thus avoiding needless correspondence.

On May 5, I think, I had occasion to examine Laviolette's "Oil of Florida Water," to find whether his claim that it "makes a water equal to Murray & Lauman's," was tenable. On July 5, after careful research, I certified in favor of the claim, and sent Laviolette a copy. He returned answer that he thought my report might have "made a better showing." In answer I invited his advice, and soon after, he sent me his "special sample" (so styled by him). This sample was unsolicited. On opening it, I remarked its peculiar smell, but while exhibiting the vial to my wife, it was accidentally broken. A few drops which remained I found to be Oil of Bay, an article which Laviolette stated in court, "*anyone* could distinguish from Oil of Florida Water." My first estimate

being thorough, and considering that the man merely wanted something more elaborately worded, I, that same night, wrote out a second report. No statement was made that the report was on the second sample; for in the first place anyone knows that an "elaborate" analysis cannot be made in five hours; in the second place, having been thorough at first, I could not subsequently be more so; and in the third place, I inferred that a mistake had been made, and the wrong oil sent me. If my first report had not seemed to him "full" enough, he should have instructed me to obtain another bottle in the open market, and not have sought to make me amenable to law by certifying supplementarily on a proffered sample. This alone was enough to arouse suspicions of the man's purpose, but I did not expect that he would think anyone (even a barber) such a fool as not to be able to distinguish the two oils, the one from the other! The trial developed the fact that the *Druggists Circular* had instigated the whole proceeding. The hearing also showed that though a strong attempt was made to get me to commit a crime, there was not evidence enough to show that it was committed.

In writing you to ask that you state the matter, I quoted you the statement of the *Tribune* to the effect that the prosecutors were satisfied as to the justice of the acquittal, a statement which I supposed veracious, as coming from such a paper.

I may be something of a "crank," but at the same time I profess to be a chemist and therapeutist. I deny most emphatically having ever certified by "influence," or to that which research would not bear out. I have worked for eight years, without pretensions, with care, and in love with my work; and (D. V.) I shall continue my labors in my humble way, and according to the best of my ability. I feel no shame, and have no compunctions of conscience. I regret that I have to ask to occupy so much of your space; and thanking you for your past confidence in me, I trust to be able to merit its continuance.

Willard H. Morse, M.D.

Westfield, N. J.,
Oct. 16, 1888.

[We think it only fair to permit Dr. Morse to reply in our columns to the comments on his case published in our issue of October 13. We have nothing to add to what we have said, and what he now says, except that we have no pleasure in expressing censure, and that we sincerely hope he may merit and secure the good opinion of right-minded men.—Editor of the Reporter.]

Electrolysis for Stricture of the Urethra; Death.

To the Editor.

Sir: I have had a case of suppression of urine and death following electrolysis for stricture, which I wish to report. The case so closely resembled an attack of pernicious ague—"sinking chills"—that I would like to hear comments upon it from yourself or some of your readers.

On the 20th of August, 1888, I saw the patient in consultation with a physician of a neighboring town. The patient was 56 years old, a cattle-breeder and importer doing an extensive business. Ten years ago he contracted an inflammation of the urethra, whether specific or not those of us who saw and treated it were undecided. The canal had a dry, red appearance, with very little if any suppuration. It would readily yield to treatment and apparently get well. But a glass or two of beer or whiskey, or any over-exertion, would start it up again.

It did not seem to be communicable. His business required much traveling, and he was treated for it in various parts of this country and Europe, always by the best practitioners obtainable under the circumstances, he never trusting himself in the hands of the so-called specialist who infests all our larger cities. After six or seven years he noticed that his stream of urine was becoming smaller. While in the mountains of the West last summer the symptoms of stricture became very annoying.

I found the meatus corresponding to No. 5 American scale, with the normal urethra behind it measuring 15. The meatus was incised and a No. 12 sound was passed, and encountered a stricture just behind the bulb. The patient showing signs of shock, no attempt was made to pass a sound any farther. It was agreed that his attendant should keep the meatus patulous by passing through it a test-tube, No. 15 in size, and when the incision was sufficiently healed send him to my office for electrolysis.

On the 31st of August he presented himself, saying that he had had the ague on the 29th—two days before. I found that a No. 2 Tiemann bulbous rubber bougie was the largest that could be passed into the bladder. Using my smaller olive, a No. 11 English, it was passed down to the stricture and connected with 12 Law cells, which were slowly increased to 20. (They were not very active, not having been charged for 2 years.) The bougie passed through this stricture in seven minutes, encountering another three-quarters of an inch beyond.

The latter was passed in the same length of time. The olive was then withdrawn above the first, and passed through them again, taking four minutes' time. Shock was very slight, only a little pallor; the pain was insignificant.

He left my office immediately and rode twenty-four miles on a train, feeling no inconvenience except scalding on urinating. After attending to some business, instead of staying in town as he was expected to, he mounted a road-cart to ride three miles into the country. While on the road he was taken with a very severe chill and sudden prostration. When his physician reached him he had the appearance of profound shock: vomiting, cold extremities, clammy perspiration, pulse scarcely perceptible and only forty per minute. He passed two ounces of bloody urine. By energetic treatment a partial reaction was brought about. The temperature in the mouth for a short time was above normal, but did not remain so more than an hour.

I saw him at 5 P. M. Sept. 1. His temperature was then 96°; pulse 84, very weak, and easily compressed. Respiration 24 and jerky. The stomach was irritable, the bowels constipated. He was given strychnia, strophanthus, atropia and whiskey hypodermically; whiskey, digitalis, tincture of cantharidis, sulphate of quinine, in a pint of hot water by the rectum. The latter was repeated five or six times in fifteen hours. The hot water was all retained and apparently absorbed. Calomel and bismuth were given by the mouth. Dry cups were placed over the kidneys and artificial heat applied. Nothing, however, did any good. He gradually sank and died at 4 P. M. Sept. 2. Two hours before death a catheter was introduced and half an ounce of bloody urine withdrawn.

Now, how much did the electrolysis have to do with the fatal result? The case closely resembled in its symptoms the "congestive chills" we used to encounter in this vicinity over thirty years ago.

A. Ady, M.D.

Muscatine, Iowa,
Sept. 20, 1888.

—Dr. J. J. Leppa, says the *Medical Record*, October 20, 1888, has been sued for malpractice by an Italian woman to whose son he had given chloroform and ether for eclampsia. The anæsthetics controlled the convulsions, but the boy died.

Notes and Comments.

Antipyrine in the Pain of Dysmenorrhœa.

Dr. Windelschmid states in the *Allgemeine med. Central-Zeitung*, No. 53, 1888, that the sedative action of this agent has given brilliant results in the pain of dysmenorrhœa. He prescribes it in doses of 30 grains in clyster before and during menstruation. Generally its action was manifest after one-quarter of an hour, but in one case it had to be repeated in twelve hours. Its action was strikingly favorable, especially in two cases, in which all the resources of gynecology, both external and internal, had been exhausted in vain. These patients for eight days, before and during the period, suffered with violent pains and cramps. Clysters were used in the morning and evening, and in the following evening. Generally the analgesic action, even in children, was associated with a narcotic effect. Disagreeable complications, with the exception of profuse sweats and often slight retention of urine, were not observed. A glass of wine or beer was often given to prevent collapse. Urticaria was observed in the case of a boy seven years old, who had been given four and one-half grains of antipyrine by the mouth. It was accompanied with high fever, and lasted about twelve hours.

Union by First Intention of Wounds Exposed to the Air.

A correspondent of the *Medical Press and Circular*, August 1, 1888, reports from Paris that M. Léon le Fort had recently attacked the method of Lister, which he taxed with exaggeration. According to the English surgeon, the air contained germs which excited suppuration, and in order to destroy these ferments, phenic acid was used under every conceivable form. Reunion by first intention was sought, in order to prevent the suppuration. His doctrine (M. le Fort's) attributes no evil influence to the air in the propagation of purulent infection, but to the fingers, instruments, and sponges used in operations. He applied himself to prove that air was innocuous, and for that purpose left all his wounds from operations, some of which were major, exposed to the air during the whole course of the operation and for some time afterward. Reunion by first intention always took place, and without suppuration.

Formulæ for Creasote.

Dr. Keferstein gives some formulæ in the *Therapeutische Monatshefte*, September, 1888, which have proved useful in his practice. The following formula, he says, gives a clear mixture which tastes and smells decidedly better, and is also cheaper, than the formula suggested by Bouchardat, which contains Malaga wine :

℞ Creasoti . . . . . ♏xx
Spir. vini rectificat. . . . . ʒvi⅓
Aq. cinnamomi . . . . . ʒiiiss
Syr. cinnamomi . . . . . ʒvi⅓
M. Sig. A tablespoonful three times a day, increasing one tablespoonful weekly.

The following formula is for administration of the creasote in pill-form :

℞ Creasote . . . . . ʒi
Powd. althea root . . . . . ʒiss
Licorice juice . . . . . ʒiss
Mucilage of acacia, q. s. ut fiant pil. No. 120; coat with gelatine.
Sig. Six pills three times a day.

When there is much cough and diarrhœa, the following may be given :

℞ Creasote . . . . . gr. xv
Acetate of lead,
Opium (pure) . . . . . āā gr. ivss
Licorice juice . . . . . ʒiss
Mucilage of acacia, q. s. ut fiant pil. No. 50.
Sig. Five pills three times a day.

Five pills contain one and one-half minims of creasote.

Instead of giving the creasote in cod-liver oil, Keferstein has the following emulsion made, which can be taken even by children :

℞ Creasoti . . . . . ♏xx
Solve in
Olei amygdalæ . . . . . ʒviiss
Pulv. acaciæ . . . . . ʒv
Aq. destil. . . . . ʒiiiss
M. ft. emulsio. Adde
Tinct. aurant. comp. . . . . ♏xv
Elæosach. menth. pip. . . . . ʒi
M. Sig. A tablespoonful from two to five times a day.

In the case of children it will be sufficient to make up half the quantity, and give a teaspoonful of it at a time. One tablespoonful of this emulsion contains one and one-half minims of creasote. If the taste of oil is detected, black coffee may be given after it.

The following formula is suitable for giving creasote in the form of drops :

℞ Creasoti . . . . . ♏xl
Tinct. cinnamomi . . . . . ʒviiss
M. Sig. Fifty drops three times a day, or one-half teaspoonful in a cup of warm milk, added while the milk is vigorously stirred.

Twenty-five drops of this mixture contain one and one-half minims of creasote. Instead of milk, wine or warm sugar and water may be used; but if alcoholic fluids are used they should be cold, while if non-alcoholic fluids are used—the best of which are mucilaginous—they should be warm. —*Wiener med. Presse*, September 30, 1888.

Antipyrine in Chordee.

Archibald Dixon, of Henderson, Ky., writes to the *Weekly Med. Review*, July 4, 1888, that he has found antipyrine of use in chordee. Given in doses of fifteen to twenty grains, in a wineglassful of water, just before retiring, he says it has effectually relieved all symptoms in three cases. In only one case was it necessary to repeat the dose during the night. He suggests for it a further trial.

Lectures at the Polyclinic.

The second annual series (Part I) of Evening Lectures on Practical Subjects will be given by the Faculty of the Philadelphia Polyclinic, at the College Building, Broad and Lombard Streets, free to members of the profession and medical students, and in the following order. The lectures begin at 8 o'clock.

Oct. 23, Prof. Henry Leffmann: "The Recognition of Poisoning."

Oct. 30 and Nov. 6, Prof. Thos. J. Mays: "Pulmonary Consumption considered as a Neurosis."

Nov. 13, Prof. Charles K. Mills: "Visual Localization."

Nov. 20, Prof. J. Henry C. Simes: "Pseudo-Sexual Disorders."

Nov. 27, Prof. S. Solis-Cohen: "The Management of Fever, with Especial Reference to High Temperature."

Dec. 4, Prof. H. Augustus Wilson: "The Preparation and Application of the Plaster-of-Paris Bandage."

Dec. 11, Prof. John B. Roberts: "Treatment of Leg Ulcers."

Dec. 18, Prof. Edward Jackson: "Failure of Sight in Old People."

Jan. 8, Prof. Chas. H. Burnett: "Some Common Causes of Deafness: Prevention and Cure of the Disease."

Jan. 15, Prof. Alexander W. MacCoy: "Observations on Certain Forms of Hoarseness."

Jan. 22 and 29, Prof. Benjamin F. Baer: "Pelvic Inflammation: Its Causes, Complications and Treatment."

Part II will be announced hereafter.

NEWS.

—The quarantine station for Philadelphia will be closed Oct. 31.

—Professor G. Ruge, of Heidelberg, has been appointed Professor of Anatomy.

—Diphtheria is epidemic in Athens, Ohio. The public schools have been closed on account of it.

—Bellevue Hospital, New York, is to have a chapel and library. The new building is now going up.

—Dr. Ferdinand E. Chatard, of Baltimore, died October 18, 1888. He was graduated from the University of Maryland in 1861.

—In a communication in the *N. Y. Medical Journal*, October 20, 1888, Dr. F. Whitehill Hinkel reports upon the use of antipyrine in acute coryza, frequent bleeding from the nose, and in hay fever.

—The *Engineering and Building Record*, October 20, 1888, protests against the pollution by sewage of the Passaic River water which is supplied to Jersey City, and declares that the water is likely to grow worse instead of better.

—The Trustees of the Hoagland Laboratory, Brooklyn, N. Y., announce that it is now open for students who desire to make original researches. Instruction in Bacteriology will be given during the winter and spring by Dr. George M. Sternberg and Dr. George T. Kemp. The fee is fifteen dollars, "which will entitle the subscriber to prosecute his studies until June 1, 1889, during as many hours of the day as he may desire."

—The *New York Sun* says: If doctors' signs are any indication of disease, the new West Side must be one of the unhealthiest parts of the city. There is a doctor's sign on every large apartment building, and they average about one sign to every five or ten private houses. The real secret of their frequency is not that there is business in that part of the city for all the doctors or for one-quarter of them, but that the recent rapid development of that section has led scores of young doctors to go there to grow up with the community in the hope of some day getting together practice enough to live. About one in a dozen of the earliest comers really did find a practice growing up around him, and a few of the West Side doctors therefore are getting rich fast, but for the rest they come, stay a few months, or as long as their capital lasts, waiting for the practice that never comes, and then they drift away; but other raw recruits from the colleges take their places and more, so that while the signs change too frequently for the neighbors to keep track of them, their number never decreases.

HUMOR.

He had Both Kinds.—Old lady (to druggist's boy)—"I want to git a leetle paint, boy." Boy—"Yes'um; face or fence?"—*Life.*

Friend (to Congressman's wife)—"Is your husband a man of sedentary habits?" Wife—"Of course not. He hasn't touched a drop in 15 years."—*Washington Hatchet.*

Should you upset a bottle of castor oil on the carpet the best treatment for removing the spot is to place the bed over it. This is both cheap and efficacious.—*Ledger.*

Terribly Broken.—"And are you really so badly broke, my friend?" he said, as he tendered the tramp a penny. "Broke?" was the bitter response. "I'm as badly broke as the Ten Commandments."—*Life.*

Invalid—"I have been here at these springs, doctor, six weeks, and I don't see that the water has had the slightest effect." Dr. Candid—"You must have patience. There was a man here last season who didn't die until after he had been here two months."—*Texas Siftings.*

A Wise Precaution.—Brown—"What have you got in the bottle, Robinson?" Robinson—"Ether." Brown—"What are you going to do with ether?" Robinson—"That big duffer Jones has threatened to whip me on sight; and as soon as I see him coming, I'm going to take it. I don't propose to suffer if I can help it."—*Puck.*

OBITUARY.

JOSEPH WARRINGTON, M.D.

Dr. Joseph Warrington, whose death was announced in the Reporter Oct. 20, died at Moorestown, N. J., at the advanced age of eighty-three years. He was a famous physician years ago before he gave up active work. He was graduated from the University of Pennsylvania in 1828, and began the practice of medicine in Pennsylvania, continuing in practice until 1854, when he retired to his farm near Moorestown. He was one of the founders of the Philadelphia County Medical Society and the State Medical Society of Pennsylvania, and of the Philadelphia Lying-in Charity.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SOLUTION FERROUS MALATE.

(Amer Phar. M'f'g Co.) 4 Grs. to Fluid Drachm.

DOSE —30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat, and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

Solution-Salicylate of Iron

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful four times a day.

An unfailing remedy in acute or chronic Rheumatism, where deformity has not yet resulted. Has also been prescribed with great satisfaction in other affections where Salicylic Acid, Bi-carb. Sodium and Ferrous Malate are indicated.

Ferrous Malate, Gentian & Cinchona

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

FOR THE INSANE.

CINCINNATI SANITARIUM.

PRIVATE HOSPITAL AND RESIDENCE.

(Incorporated 1873.)

Proprietary Interest Strictly Unprofessional.

Both sexes and all classes of mental and nervous diseases provided for.

Forty minutes by rail from C. H. & D. depot, Cincinnati. Address,

ORPHEUS EVERTS, M.D., Sup't.

COLLEGE HILL, OHIO.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

PROF. ALFRED STILLÉ, PROF. WM. GOODELL, PROF. D. HAYES AGNEW, PROF. H. C. WOOD, PROF. R. A. F. PENROSE, PROF. WM. PEPPER, University of Pennsylvania, PROF. J. M. DACOSTA, PROF. ROBERTS BARTHOLOW, Jefferson Medical College, PROF. CHAS. K. MILLS, Philadelphia Polyclinic.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

A NEW STYLE OF BI-FOCAL LENSES.

BY GEORGE M. GOULD, M.D.,
PHILADELPHIA.

The adjustment of spectacles to a presbyopic person who also requires a different lens for distant vision, is always attended with vexation to both physician and patient. One thing that renders it peculiarly difficult is that the problem is different for every patient. Women as a rule look at the matter from a standpoint quite different from that taken by men; and among the latter, as well as among the former, the peculiar habits, business, disposition, and other personal peculiarities always have to be considered. In all cases the first question to be settled is whether or not two distinct pairs of spectacles (or nose-glasses) will prove more satisfactory than a single frame with bi-focal or Franklin lenses. If the patient is a woman this question speedily resolves itself into one of personal appearance, and it is highly important to recognize this fact. The belief is yet widely prevalent that spectacles are a sign of on-coming age, and they are therefore frankly and thoroughly hated by many who desire to keep the unpleasant subject from intruding itself.

> "Though the coming on of crows-feet
> And the turning back of beaux' feet"

are evident facts, many women will endure headaches and imperfect vision, and even forego reading, rather than wear glasses of any kind, least of all, spectacles. As a consequence, the question, paltry at first sight, has a medical and serious bearing. If, therefore, it become apparent that spectacles are held to be another sign of the odious ravages of years, it may be best to drop the subject as deftly and promptly as possible. But in some instances we must not give way before strongly and clearly stating the probable consequences. Where the occupation of the patient demands frequent and continuous changes from near-work to distant vision, and *vice versâ*, then, if possible, vanity should be overcome. For example, in the case of a school-teacher, it is in the highest degree vexatious for her to change glasses every time she has to look from book to scholar, or to the blackboard. There are also certain kinds of clerical work, and certain professional occupations and artistic employments which follow the same rule. Sometimes spectacles may be accepted for the more continuous, or the more private work, whilst nose-glasses or lorgnettes are used for the drawing-room and the street. I have known as many as three or even four different styles of glasses to be used at appropriate times by one person. It is at once amusing and pathetic to see a woman with a low, flat, nasal bridge, pretending to be successful in her struggles to give her aristocratic *pince-nez* a firm hold. But in the more resigned, in those of whom old age has taken clear possession, either *vi et armis*, or with placid welcome, the trouble of changing glasses makes it easy to show the advantage of the Franklins. For such, and for most men, the bi-focal lenses are certainly to be advised.

There are three styles of bi-focal lenses: the first is the well-known and time-honored one invented and worn by that ingenious and wise philosopher, after whom all bi-focal lenses should be named. This consists in two centred lenses, the dis-

tance lens above, the reading below, the straight line of their junction being horizontal through the centre of the frame. This is shown in Fig. I. The objection to this is its unsightliness, the line being very conspicuous. Lesser objections also were, that no distant vision downward was possible, and the spectacle must be rimmed. To obviate the unsightly line of junction,

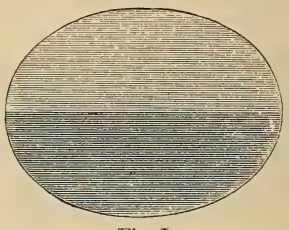

Fig. I.

(*The line of junction is not so conspicuous here as in the spectacles*).

there has been largely used a lens ground from a single and solid piece of glass, the lower or reading lens being crescent-shaped with its concave aspect up, and filling the greater part of the whole space. See Fig. II. Vanity was wholly responsible for this absurd invention, the objections to it being striking and numerous. A glimpse of the ground near the feet was entirely impossible, as much and even more so than in the older style. Moreover, lateral vision was cut off by the horns of the crescent, and the field of vision for distance, which it is desirable to have as large as possible, was reduced to a narrow space, with the valuable sides and inferior angles wasted. To emphasize the absurdity of the whole, the unavoidable prismatic effects of the lenses thus made

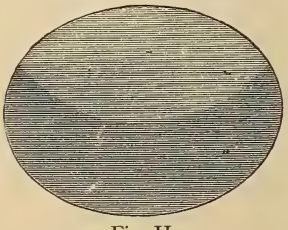

Fig. II.

rendered them so uncomfortable that many could not endure them. Yet another aspect of this question is decidedly medical, or to speak more accurately, surgical. The inability to see plainly the inequalities of the ground near the feet, or the steps of the stairs, etc., frequently resulted in missteps and falls, or at least kept the patient hampered and groping in his walking.

About three months ago I conceived the plan of reversing the position of the crescentic or semi-circular near-lens so that the bulk of the whole lens would be kept for distant vision. The plan is shown by the annexed drawing, Figure III. Upon sending my order to a prominent optician I was told that the plan had been unsuccessfully tried. I have since learned that other opticians had made one or two pairs of such spectacles, with indifferent success. Some people liked them very much, others could not wear them. So, though original enough with me, the idea had already been realized; to whom the credit of the first invention and introduction is due (a small matter) I do not know. But I am convinced that the plan is a most excellent one and worthy of recommendation. Against the advice of opticians, I have persisted in experimenting and ordering them for my patients, and now have several patients wearing them with a satisfaction they never had with any other style. The lenses are centred, there is no prismatic effect, and by the slightest turn of the head when looking down the ground

Fig. III.

in front of the feet can be seen through the distant lens. The vision sideways is, of course, perfect. I believe the failures referred to in the attempt to use them were due to the disproportionate size of the lower lens, to the clumsy manufacture of the whole, to imperfect adjustment to the eyes, or to impatience on the part of the wearer. These are all important points. The size of the reading lens may in some cases be smaller or larger than that given in the cut, according to the occupation, the contour of the face, the peculiarities of habit, of holding the head, etc., of each patient. In most cases the proportions given will not be far wrong. It is also self-evident that such a pair of spectacles will require the utmost exactitude of adjustment to the contour of the nose, pupils and face. As to method of inserting or adding the stronger lens to the distant one, manufacturers will probably differ. As usually ground, it is beveled and set into a ground-out and grooved space in

the larger lens. This makes it necessary that the glass shall be pretty thick, renders the line of junction very conspicuous, and makes a rim to hold the two pieces firmly in place unavoidable. I have been much pleased with an ingenious method devised by Messrs. Wall and Ochs, manufacturing opticians, whereby most of these objections are obviated. The spherical presbyopic lens is reduced in thickness to a mere film of crystal, and is glued with Canada balsam to the lower and inner side of the unmutilated distance-lens. In this elegant manner the lenses are rendered very light, the added lens is very inconspicuous, and the spectacle rim is dispensed with, the whole presenting a neat and workmanlike appearance. Finally, it must not be forgotten that the patient must be repeatedly cautioned about the preliminary period of discomfort in "breaking them in." It requires no little persistence and patience in wearing them before one learns how to use them best. To some extent, the whole carriage of the head and the innervation and habits of many muscles are changed. I am in the habit of making every patient promise he will give them a month's trial despite all vexation and discomfort. Within this time he grows most enthusiastic in their praise.

119 South Seventeenth Street.

CONVULSIONS IN CHILDREN, WITH SPECIAL REFERENCE TO ETIOLOGY AND TREATMENT.

BY C. L. DODGE, M.D.,
KINGSTON, N. Y.

The term convulsion, or eclampsia, is here used in a somewhat restricted sense. I cannot go as far as some writers who believe this condition to be in most instances epileptoid. I agree with Nothnagel[1] who asks: "What is there now remaining of what was formerly eclampsia? Are we altogether justified in still retaining the name? We believe so, and are of the opinion that the title eclampsia should be reserved as the name of an independent affection, which, it is true, can at present be defined only by its clinical symptoms. We propose that the designation eclampsia should be made use of for those cases of epileptiform spasms which, independent of positive organic diseases, present themselves as an independent acute malady, and in which, so far as our present knowledge allows us to judge, the same processes arise, generally in the way of reflex excitements, and the same mechanism in the establishment of the paroxysms comes into play, as in the epileptic seizure itself." Allan McLane Hamilton[1] says: "If any distinction at all be made, it should be one founded upon the fact that epilepsy is usually an organic disease, or, more precisely, a disease which when established is dependent upon some disorganization, while eclampsia is used to express those seizures of a purely functional nature."

Definition.—Convulsion (from the Latin *convello, convulsum,* to pull violently), synonym Eclampsia, is an acute nervous affection occurring in paroxysms, during which the patient loses consciousness, the muscles of the body are spasmodically contracted and the limbs first stiffened and twisted, then agitated by irregular involuntary movements: in a word, an affection in which there are clonic spasms. Convulsions occur in a great variety of diseases and are dependent upon various causes. The classification into three forms adopted by J. Lewis Smith is the simplest and most convenient with which I am acquainted. He says:[2] "The term essential or idiopathic is used when the convulsions have no appreciable anatomical character, that is, when there is no apparent pathological state in the brain or elsewhere, which gives rise to the attack. If the cause is disease of the brain or spinal cord, it is termed symptomatic. If eclampsia arise from local disease elsewhere than in the cerebro-spinal axis, as from pneumonia, the term sympathetic is employed."

Causes.—The causes of the convulsions of children are many and varied, and one object of this paper is to endeavor to sift out the most important ones, that treatment may be more rational. First among predisposing causes is age The affection is peculiar to young children. Probably the age at which convulsions most frequently occur is from six months to thirty months—the period occupied by dentition. I do not, however, regard dentition as the most frequent cause, but think that the occurrence of convulsions at that time is due to the fact that the nervous system of the child is then so much more susceptible and impressionable than it is in adult life, owing doubtless to rapid growth of the child.

[1] Cyclopædia of the Pract. of Med., by von Ziemssen. Vol. xiv, p. 301. American Edition.

[1] Pepper's System of Medicine. Vol. v, p. 465.

[2] Diseases of Children, article Eclampsia.

The form of eclampsia under consideration is rare after seven or eight years of age.

Hereditary tendency is an important factor in the etiology of convulsions of children; and in the majority of cases the predisposition is said to be transmitted by the mother. The weight of authority seems to be against the view that puerperal convulsions in the mother leave a tendency to convulsions in the child. It is nevertheless true that eclampsia is frequent in certain families, seemingly through inheritance; it is as much so, at least, as insanity or phthisis. Children with rickets are very susceptible to influences that produce convulsions. Huhlings Jackson, quoted in the *Medical News*, August 7, 1886, says: "The softness of the ribs in rickets deprives the diaphragm of its normal support, and seriously embarrasses respiration. The respiratory centre is thus perpetually bathed in blood so highly venous that it requires only a slight additional stimulus to throw it into furious action. A coughing fit for example will, by checking the already imperfect respiration, decide the onset of a convulsion."

The exciting causes of eclampsia are very many. It occurs as a symptom in nearly all cerebral diseases: hypertrophy of the brain, thrombosis of the cranial sinuses, congestion of the brain, cerebral hemorrhage, etc. The most frequent cause, however, I believe to be irritation of the gastro-intestinal tract produced by the ingestion of indigestible substances. In a record of twenty-four cases of convulsions, all but four were plainly caused by indigestible food or over-feeding. One great difficulty in ascertaining the cause in many cases, is that parents dislike to admit that anything improper has been given to the child, and often they are entirely ignorant of the fact. Children frequently have these unwholesome articles given to them without the knowledge of the parents. At holiday times it is always well to make the strictest inquiries of all concerned; if the parents can give no information, perhaps someone else can. To illustrate, last Fourth of July I was hastily summoned to see a little boy, two and a half years old, who had just had a severe convulsion and seemed to be threatened with another one. I inquired of the parents if he had eaten anything that might be difficult of digestion. The answer was no. I then inquired of the older children if he had had any nuts or fruit. His sister then stated that some time in the forenoon he had eaten an orange, "skin and all." An emetic soon proved the truth of her statement, a large portion of the orange, with the rind, being vomited. Another case was that of a child eighteen months old, whose mother had given it a quantity of Bologna sausage, the child having no back teeth yet; there was small cause to wonder at the consequences. Smoked beef also is a frequent cause, it being such a common article of diet. Meat in any form should never be given to children until they have all their teeth. The worst case of convulsions I ever saw was caused by eating stewed prunes. At holiday time, and after children's parties, we always look for some cases of this kind. Quite a number of cases are on record in which the child died in a convulsion, and at the autopsy no cause could be found other than a stomach well filled with undigested food. Giving to young children a little, and what is worse, a good deal of everything, is very bad practice. Nuts, candies, unripe fruit, rich cake and pies, hot bread, and meat when the child has not sufficient teeth to masticate properly, are the exciting causes in a large proportion of cases of convulsions. Indeed, over-feeding and improper food are the causes of nine-tenths of the convulsions of children, if we exclude diseases of the brain and acute fevers.

Worms also are said to be a cause, but I have never seen a case in which I could satisfy myself that such was the fact. I have on several occasions at the earnest solicitation of the parents, who very frequently believe that worms are a cause of spasms, and that treatment should always be directed against them, administered a vermifuge, but thus far with negative results. I am well satisfied, however, that very many more cases of eclampsia are occasioned by the indiscriminate use of the various patent vermifuges with which the market is flooded, and which are administered on the slightest provocation. I have seen several cases in which there seemed to be no other adequate cause, the "worm medicine" alone being sufficient to account for the fits. I recall one case, that of a boy four years old, whose death in my opinion was due to an overdose of santonin. It must be remembered that the ignorant lower classes give these remedies in large doses and without any judgment, and with the idea in many cases, that they must persist in the use of the medicine until they "fetch the worms." I do not wish to be understood as denying *in toto* the possibility of worms being a cause of eclampsia; but I do insist that, by the laity at least, they are given undue prominence as a causative factor. This is not

merely an individual opinion, but it is held by some of the highest authorities. Prof. Flint says[1]: "That they (worms) may give rise to convulsions, epileptic paroxysms, chorea, and other affections of the nervous system, as is generally supposed, must be considered as by no means established."

Dentition.—The opinion in the profession once was, and in the community still is, that dentition is the sole and sufficient cause of many of the diseases of childhood. Especially is this true with reference to spasms, or fits as they are popularly called. Physicians at the present day are very much divided in opinion as to the true position of dentition in infantile pathology. Some authors believe that the evolution of teeth when painful and difficult has much to do with many of the ailments and disorders of early life. Others affect to believe that dentition is purely a physiological process, and therefore does not require the interference of art. They say that it is not pathological and that surgical measures are uncalled for. As in all other medical matters, I think it is wise to avoid extremes; a happy mean is usually safest and best. Why there should be such extremists it is hard to understand. Anyone who can recall the eruption of his first "wisdom tooth" should, it seems to me, have clear and decided views on the subject of "teething." I well remember lying awake all night while cutting one of mine. I was feverish, restless and in pain, and this is precisely the condition of the child when cutting teeth. Add to this that the child's whole nervous system is rapidly undergoing development, and is at this time extremely susceptible to pain, and it will seem not at all strange that convulsions and other disorders are developed as a consequence. Difficult dentition is perhaps not so often a direct as a predisposing or coöperating cause, producing a sensitive state of the nervous system which requires but a slight additional stimulus to determine a convulsion. Cases do occur, however, in which the pain and nervous excitement caused by the advancing tooth seem to be the only causes discoverable. This is especially true where several teeth penetrate the gum at or about the same time.

West and Reynolds are of the opinion that convulsions occur in children as delirium does in adults; in other words, that they are the most common expression of neurotic instability. Acute inflammations, especially of the respiratory apparatus, are sometimes causes; one of my cases occurred in the beginning of an attack of pneumonia. Convulsions are also said to occur at times in severe coryza. They are often seen in the commencement of small-pox and scarlet fever, and in the course of the latter disease. They are a common complication of pertussis and are also witnessed in some forms of malarial fever. One of my cases seemed to be dependent on malarial poisoning, and was finally cured with quinine. In young children, burns and scalds are often followed by severe spasms, frequently succeeded by coma and death. Among other causes may be mentioned constipation, dysentery, urinary calculi, both renal and vesical, and uræmic poisoning, as the result of scarlatinal nephritis. Dr. Weir Mitchell[1] states that he has seen children reduced to a state of pitiable nervousness, with feebleness of will and convulsive states not epileptic, owing to unsuspected albuminuria. The mysterious changes effected in the milk of the mother, as the result of violent emotions such as fright, anger, or grief, have been known to cause eclampsia and even death in the child. Preputial adhesions and a narrow prepuce are quite common, and are *sometimes* the cause of reflex disturbance, as the result of constriction or adhesion of the prepuce; but of late years the importance of these consequences has been greatly over-estimated, and this has too often led to rash and unwarranted surgical interference. Comparatively few children are ever inconvenienced by this defect, and doubtless there are hundreds to-day who are none the worse because of this slight anatomical peculiarity. Allan McLane Hamilton[2] says: "The alleged sexual causes of epilepsy are many and some of them very doubtful." This applies with equal force to the eclampsia of children. In my opinion sexual derangements are a very infrequent cause of "reflex neuroses."

Relations between the Convulsions of Childhood and Epilepsy.—On this subject Dr. H. C. Wood[3] writes as follows: "The question of the relations between epilepsy and the convulsions of childhood, is one of great importance. As already stated, I do not believe that the diagnosis between these two affections is to be made out by the symptoms of a single fit. Moreover, it seems to me positively established by clinical experience that the tendency to convulsions in the child is closely associated with the epileptic

[1] Practice of Medicine, p. 513.

[1] *Medical News and Library*, Dec., 1877, p. 31.

[2] Pepper's System of Medicine, Vol. v, p. 473.

[3] Nervous Diseases and their Diagnosis, p. 109.

diathesis, and that in many cases accidental convulsions are the commencement of a life-long epilepsy. In a very large proportion of the cases of epilepsy there is a history of repeated convulsions during early childhood; and there must be inherent differences in the nervous constitutions of children living under exactly similar conditions, some of whom frequently suffer from convulsions, whilst others pass unscathed. Some children are evidently born with the convulsive tendency, which in many cases is so firmly fixed in the nervous system that it cannot be affected by any mode of life or treatment; its possessor is doomed from birth to a hopeless epilepsy. I believe that there is a second class of cases in which the epileptic tendency exists, but in so slight a degree as to be controllable by hygienic and medicinal treatment. Under these circumstances the child may suffer from repeated attacks of accidental convulsions and become epileptic, or by great care the early convulsions may be prevented, and the nervous system allowed to harden to the normal mould." While it is unquestionably true that in many of the cases of epilepsy there is a history of convulsions during early childhood, it is equally true that hundreds of children have convulsions who never develop epilepsy when grown. I have made numerous inquiries on this subject, and could give a very long list of personal acquaintances who had convulsions during childhood, but have never had the first symptom of epilepsy. J. Lewis Smith[1] says that at the Bellevue Hospital Outdoor Poor Department he has carefully observed cases brought there during the last six years, and has been unable to convince himself that there is any connection between the convulsions of young children and epilepsy of later life. The age at which epilepsy is liable to develop he says is from five to seven years, but he regards the two as independent conditions. Hammond[2] also says: "These latter (convulsions of infancy) may pass into epilepsy; but, if they do not I have never been able to find a single case in my experience in which epilepsy ensuing in adult life has been preceded by the ordinary infantile convulsions." Flint[3] says: "Facts showing how frequently epileptoid attacks occur without being followed by epilepsy, are wanting, but it is certain that the latter by no means invariably follows." I do not wish to imply that epilepsy does not occur in young children, as that is an admitted fact, two of my own cases being undoubtedly epileptic; but I wish to protest against the idea that if a child has a convulsion it is likely to become an epileptic, for I do not think facts warrant any such assumption.

Anatomical Characters.—It is obvious that a disorder arising from so many different causes, and being dependent so frequently upon other diseases, must vary greatly in its morbid anatomy. In those cases of acute inflammation of the lungs or other organs attended with rapid pulse, pulsating fontanelle, and other evidences of arterial excitement before convulsions occur, active congestion of the brain would seem to be the condition present, and the obvious cause of the fits. At other times passive congestion of the brain plays a part in the causation, as is seen in a paroxysm of whooping cough, for instance. In the contagious diseases, such as small-pox and scarlet fever, the convulsion is believed to be due to the action of the specific virus on the cerebro-spinal system. In cases dependent upon malaria, some think the occurrence of convulsions is due to the poison itself, others to the high temperature. In the case that I have recorded the temperature was not high, and I am inclined to believe that the true cause was congestion of the brain as the result of a severe chill; young children seldom shake hard, but the congestion of internal organs takes place just the same.

When the eclampsia is dependent upon disease of the brain, congestion plays an important part associated, perhaps, with effusion, or compression of the brain from some cause. One of my cases was undoubtedly due to cerebral hemorrhage. The child was eleven months old and in good health; it was playing on the floor in the morning when suddenly, without any warning, it was taken with a convulsion from which it never rallied, death taking place about six o'clock the same evening. The right side was paralyzed, and it died comatose.

Symptoms.—I will not attempt an elaborate description of a convulsive attack; it is too familiar to every practitioner of medicine. As to the premonitory symptoms, I think they are rarely observed, for the reason that in the majority of cases there are none. In acute diseases, fevers, and inflammations the general symptoms of these disorders are so prominent that attention is diverted from any slight nervousness or irritability which

[3] Practice of Medicine, p. 757.

at other times might be noticeable; and as it is in this class of cases chiefly that we observe prodromata, I think it can be safely said that the latter are seldom recognized. The prodromic stages of the various affections that are sometimes complicated with convulsions, would be observed as a matter of course; but these, I hold, should not be termed premonitory symptoms of eclampsia—they are properly the premonitory symptoms of the primary disease, whatever this may be.

Eclampsia may be general or partial. Partial eclampsia is the more common form. Death may occur from cerebral congestion, which if continued is liable to end in effusion of serum or extravasation of blood, when all convulsive movements cease but consciousness does not return. The first attack is rarely fatal. The mode of death is usually in coma.

Diagnosis.—The diagnosis of eclampsia is generally easy. It is most likely to be confounded with epilepsy. As regards the seizure itself, there is no appreciable difference; but epilepsy is rare under six years of age, and convulsions are frequent. The probabilities are always against epilepsy in a child under six years of age. If there is a history of exposure to scarlet fever, smallpox or malarial poisoning; or if symptoms of inflammation of the lungs are present; or if the child is teething, or suffering from obstinate constipation, the cause of the trouble becomes apparent. If there is a history of overeating, or of the use of indigestible food such as stale or green fruit, nuts, candy, etc., it becomes perfectly clear that the case is one of eclampsia.

Prognosis —Symptomatic eclampsia is always serious. If convulsions occurs in the course of a cerebral disease it indicates the approach of death; but if at the commencement, some recover. The recurrence of it, whatever the cerebral disease, is an almost certain prognostic of death (J. Lewis Smith).[1] In sympathetic eclampsia the prognosis obviously will vary with the primary disease which causes it; it will also vary according to the stage of that disease. Convulsions occurring at the commencement of an eruptive fever generally subside without untoward symptoms, and the fever pursues a favorable course. Occurring after the appearance of the eruption, however, it is always a grave symptom, and is usually premonitory of a fatal termination.

J. Lewis Smith states that he has never known a patient with scarlet fever recover who had convulsions after the rash had covered the body. J. F. Meigs, however, relates one favorable case; he also states that in convulsions consequent on pneumonia or a burn, more die than recover. One of my cases occurred at the commencement of an attack of pneumonia and recovered. It is said that death does not ordinarily occur from one attack, which is undoubtedly true. One of the cases which I have recorded, however, died in the first fit; but this was unquestionably due to cerebral hemorrhage. Convulsions occurring in the course of whooping-cough are of very serious import if they be not associated with dentition, or some disturbance of the alimentary canal. In eclampsia caused by errors of diet the prognosis is good, as it is also when dentition seems to be the exciting cause.

Treatment.—In the treatment of no disease is it more important to ascertain if possible, the cause, than it is in convulsions of children. I endeavored to show under the head of causation, that a very large proportion of convulsive attacks originated in the condition of the stomach or bowels, and for this reason, emetics are frequently indicated. In all young children in whom brain disease, acute fever or dentition can be excluded as exciting causes, an emetic should be given. The physician should not be satisfied with a teaspoonful of syrup of ipecac, but should give ten drops of fluid extract of ipecac, or ten grains of the powdered ipecac in half a wineglassful of warm water, and repeat in fifteen minutes if necessary. When the child is past swallowing I would suggest the use of apomorphine hypodermically. If the emetic acts promptly in removing the offending substance, the convulsions in most cases will be arrested, and will not recur. An emetic has some peculiar effect in controlling the spasmodic movements, probably through muscular relaxation, apart from the mere removal of irritating substances from the stomach. If there is reason to suspect that a portion of the indigestible matter has passed into the bowels, an enema of soap and water will usually produce a free and speedy evacuation, and will often disclose the cause of the spasms by the expulsion of seeds and half-digested fruit, which the child has eaten. If the enema fails it is good practice to administer a cathartic, and calomel is one of the best; it is easily taken dry with a little sugar. Castor oil is preferred by some in very young and feeble children. These measures should be followed by full doses, in proportion to the age, of bromide of sodium, which is very

[1] Diseases of Children, p. 393.

much more acceptable to a weak and irritable stomach than bromide of potassium. I have found this to be true on several occasions, and decidedly prefer the sodium salt in these cases. If the convulsions do not cease by the use of the above measures, chloroform should be given by inhalation; it will arrest convulsions when nothing else will, and usually very little is required. I have seen the convulsions cease as soon as the child became anæsthetized, and they have not returned. It should be used only during the convulsion and withheld as soon as the spasmodic movements cease. I have never seen any untoward results follow its use, in cases of this kind. Chloral is also highly spoken of, but I have not had much experience with this drug.

The use of opium in this as in many other diseases of children has given rise to much discussion; the teaching of the late Dr. Beek, never to give opium to children under four or five years of age, has deterred many from using this valuable remedy. Modern writers on diseases of children do not prohibit the use of opium. It is not so very many years ago that opium was held to be contra-indicated in bronchitis and pneumonia. There can be no doubt of its good effect in certain cases, especially when the child seems to be in pain, or when diarrhœal troubles show the cause to be in the intestines.

With reference to the use of the hot bath, I am inclined to think that its use should be somewhat restricted; that is, I would not recommend it as a routine treatment, especially when it is to be left to the parents or friends to make use of. It is held by some that the child is liable to have one or more convulsions while in the bath, and that the agitation incident to the giving of the bath adds to the excitement of an already disturbed nervous system. The great object in treatment is to keep the nervous system as free as possible from agitation. The force of this objection is lost if the child be unconscious, and the hot bath is often a valuable means of inducing muscular relaxation sufficient to enable the child to swallow. I am convinced that it is often productive of more harm than good, when in the excitement of the moment the water is too hot or too cold; the child is frequently kept in the bath after the water becomes cold, thereby inducing a chill, which adds to the cerebral congestion already present. When given under the supervision of a physician in appropriate cases I believe it to be a beneficial agent. Putting the feet into hot mustard-water can certainly be productive of no harm. It should be continued from five to twenty minutes according to the severity and duration of the attack, cold applications being made to the head at the same time.

In convulsions arising from dentition, chloroform is the best remedy to arrest the spasm, after which, if the gums be swollen and hot, and the child is feverish, scarification is proper, followed by a mixture of bromide of sodium and opium in the form of paregoric. This is the form of eclampsia in which opium in small doses combined with the bromide is especially indicated. What is the condition in these cases? There is pain—intense, sometimes, for an infant—combined with nervous excitement. What treatment could be more rational than anodynes and nerve sedatives? And clinical experience proves this to be correct reasoning. Some prefer chloral with the bromides, but I think this combination more appropriate in cases in which the convulsions continue if chloroform is not used. The immense doses of morphine used in uræmic and puerperal convulsions would seem to disprove the alleged dangers attending its use.

When the convulsion occurs at the commencement of an eruptive fever or pneumonia, no special treatment is required, beyond the addition of bromide to the treatment appropriate to the fever. If it occurs later and the eruption has receded, it becomes a serious complication, and active revulsive measures, as hot mustard baths, are necessary.

In dysentery or internal inflammations, counter-irritants over the abdomen, with full doses of opium in proportion to the age, and the bromides are proper. When due to malarial poisoning the convulsion should be arrested by the usual means, after which calomel, castor oil and quinine should be given to prevent its recurrence. If the child appears cold and chilly after the convulsion, opium in some form should be given till the quinine has time to have its effect. Veratrum viride I have had no experience with.

In cases due to cerebral congestion, if active a purge is indicated, but it is often better to give an enema at once. External derivative agents are also indicated, such as a warm mustard foot-bath followed by sinapisms to the back of the neck, feet, and calves of the legs, with cold applications to the head; and the bromides internally. In passive congestion the disease is not primary, but dependent upon some antecedent

condition, such as whooping cough, when the treatment appropriate to that disease should be instituted. In cerebral hemorrhage very little can be done. Cold applications to the head, mustard to the back of the neck and legs, with prompt purgation are the most that can be done. Some advocate leeches to the temples if congestion is marked. Bromides may also be given if the child can swallow.

ACUTE UNILATERAL OPTIC NEURITIS, WITH THE REPORT OF A CASE.[1]

BY G. E. DE SCHWEINITZ, M.D.,
OPHTHALMOLOGIST TO THE PHILADELPHIA AND ORTHOPÆDIC HOSPITALS, PHILADELPHIA.

Cases of sudden failure of sight in one eye, with little or no ophthalmoscopic changes, are occasionally encountered, in which the attack is attributed to exposure to cold. Sometimes in these instances congestion of the optic disk is present, and a retro-ocular neuritis has taken place. Other cases of acute optic neuritis, sometimes monocular, sometimes double, are on record. Thus Max Haadel[2] observed nine cases, some single and some double, with and without defects in the field of vision, usually with serious disturbance of sight, mostly with pronounced inflammation of the papilla and neighboring retina, in which exposure to a draught of air was the imputed cause. Periostitis at the foramen opticum was doubtful, and the absence of syphilis, sugar and albumin, lead and other poisons was assured in every case. In M. Schlüter's[3] statistics, among thirty-eight cases of neuritis and neuro-retinitis, seven are classed as primary, while the remainder are arranged as follows: thirteen of central origin; six from specific causes; four followed as the result of pathological orbital processes; two from abuse of alcohol and tobacco; two from albumin; and one each in connection with the puerperal state, after injury, from acute myelitis, and from hereditary reasons. E. Schmidt,[4] in an examination of the cases of optic neuritis in the clinic of Prof. Hirschmann, at Charkow, found, among 120 cases in which the etiology was recorded with some degree of exactness, two instances of papillitis or papillo-retinitis due to cold. Voissius[1] has recorded a case of monocular optic neuritis in a man sixty-one years old, the attack coming on as the result of catching cold during a long, wet drive. Recovery, with a hemiopic defect in the field of vision, was the outcome of the disorder. Roi[2] reports some examples of optic neuritis which he looked upon as rheumatic. They appeared monocular, were accompanied by a speedy diminution of visual acuity passing into amaurosis, but not, however, to the exclusion of a return to normal sharpness of sight. H. F. Hansell[3] describes two instances of acute optic neuritis of rheumatic origin; one monocular, in a healthy married woman, and the other double, in a man aged thirty-one. In each case there was sudden loss of vision, swollen optic disks, and under treatment a rapid return to normal visual acuity. In Dr. Hansell's paper references to analogous cases are recorded, and L. W. Fox[4] has recorded an instance of acute monocular optic neuritis. Recently R. H. Derby[5] has reported a case of unioocular neuro-retinitis in a girl whose father had had syphilis, but who had no other manifestation of constitutional taint. There was at first a central scotoma, then optic neuritis. Light-perception was lost, but under mercurial inunctions and iodide of potash the swelling of the disk, which had amounted to 7 D., subsided, and fair vision was recovered. Cases of optic neuritis without evident cause are occasionally recorded, as one by Power.[6] The patient was an anæmic lad of seventeen; the neuritis was double; albumin and syphilis were absent; the lad had had two attacks of rheumatism and his father was gouty. Friedenwald[7] describes an instance of right optic neuritis in an otherwise healthy girl of fourteen, preceded by violent headache and other symptoms indicating grave cerebral disturbance, but in which perfect recovery

followed. He classed her case with these examples of optic neuritis, referred to by Juler, and occasionally met with in young girls, the cause assigned being some menstrual disturbance, the presence of which, however, careful inquiry often fails to elicit. Usually the neuritis is preceded by severe headache, and the prognosis is unfavorable. No further reference to the many cases of neuro-retinitis described in connection with irregularities of the menstrual functions need be made. Hirschberg[1] has seen several instances of primary optic neuritis, whose course is very typical. The disease is divided into three stages: the first, characterized by great visual disturbance, with slight ophthalmoscopic appearances; the second, by diminution of the visual disturbance and very marked inflammation of the disk; and the third, usually by almost complete recovery, with pallor of the disk. The cases for the most part occur in women, but are not connected with derangement of the sexual functions. Partaking somewhat of the nature of such cases, but not without a history of exposure as the exciting cause, is the subject of this communication.

Mrs. W., forty years old, consulted me on July 11, 1888, because for a week past she had suffered from neuralgic pains in and above the eyes, most marked upon the right side. Bright light was distressing and pain followed when the eyes were rolled upward; slight tenderness was apparent when pressure was made upon the right globe. The vision in each eye was $\frac{5}{VII \frac{1}{II}}$, the amplitude of accommodation 3.5 D.; there was high insufficiency of the internal recti, so that a divergent squint was evident when the eyes attempted to fix a point 15 cm. distant. The fundus of each revealed no gross lesions, save a slight retinal haze around the upper and lower edges of the right disk, the deeper layers of which were gray. The maculas were normal and the refraction appeared to be a simple hypermetropia of 1.5 D. In the absence of any general derangement the peri-orbital pain was attributed to eye-strain, and atropia drops were ordered for the purpose of measuring the refraction error. The correcting glass proved to be + 1.5 s. and with it normal vision $\left(\frac{5}{V}\right)$ was acquired. During the application of the atropia the neuralgia disappeared. The drops were discontinued and the patient directed to return in two weeks. During the measurement of the refractive error, the patient on several occasions stated that although she saw the same number of letters with the right eye that she did with the left, she failed to see them with the same distinctness; but no changes at this time were present in the fundus. This indistinctness gradually assumed the appearance of a definite, dark area in the field of vision; the peri-orbital pain returned; and five days after the last ophthalmoscopic examination had failed to discover any changes in the disk or retina, she returned with the vision sunken to ability to count fingers, with well-marked right-sided optic neuritis. All edges of the disk were woolly and its upper margins entirely hidden, while a flame-shaped hemorrhage was situated above and to the inner side. The apex of the swelling was +3. D., the vessels were about normal in size, and the macula free from disease. The pupil was of medium size and acted sluggishly to light and shade. A few days before this time she had gone on an excursion with her children, became much overheated, and had afterward waded about in a neighboring brook. It was in the evening of this day that the neuralgia returned, the definite dark area appeared in the field of vision, and shooting pains attacked the deep muscles of the thighs. Further examination proved an entire absence of any symptoms pointing to brain disorder; the heart and lungs were normal and the patient was not anæmic; there had been no suppression of the menstrual flow, and this function was natural; no active uterine disease existed, except a slight prolapsus which was not then under treatment. The urine was free from albumin, sugar, and tube casts, and the last recent illness, several years before, had been an attack of peritonitis, from which a good recovery had resulted. Dr. James Tyson, who saw the case in consultation, confirmed the accuracy of these examinations. Syphilitic infection and the action of lead or other poisons were carefully excluded. The vision continued to sink, and on the following day was reduced to faint quantitative light-perception and the disk, if anything, was slightly more swollen. The temple was freely leeched and the patient directed to take fifteen grains of salicylate of sodium before each meal and seven and a half grains of iodide of potash, with one-twenty-fourth of a grain of bichloride of mercury, after each meal. Three days later, or on July 30, the vision was slightly improved to the ability to see the hand move, and the

[1] Hirschberg. *Centralbl. für prakt. Augenheilk.*, Nov., 1887.

pain was distinctly better. The medicine was continued and small fly blisters ordered placed upon the temple. August 1, the salicylate of sodium was discontinued, but the other medication continued, vision improved and large letters (Sn. CC) were faintly recognized. August 6, marked improvement, V.$=\frac{5}{XXXV}$; edges of the disk visible all around and only a faint remnant of the hemorrhage. August 20, neuritis had practically subsided; V.$=\frac{5}{X}$, form and color fields normal in extent; no scotomata; ordered one-twenty-fourth of bichloride of mercury after each meal. September 9, V.$=\frac{5}{VII\frac{1}{11}}$, disk pallid, and all traces of the neuritis had disappeared.

In the absence of any symptoms pointing to cerebral disturbance, with no uterine disease save a slight prolapsus and the history of a leucorrhœa no longer active; with the menstrual functions normal; with a healthy circulatory apparatus and the urine free from albumin, sugar, and tube casts, and with the direct account of overheating and exposure, we may fairly conclude that this was an instance of genuine, acute optic neuritis. The history shows that before any ophthalmoscopic changes were evident, and before there was any positive diminution in visual acuity, the field of vision was invested with a haze which afterward assumed a definite, dark form, probably coincident with the first appearance of the inflammation around the papilla and the loss of sight. Hence it is evident that the attack was in process of formation and was precipitated by the wetting of the feet and sudden cooling after an overheating. Cases of optic neuritis apparently due to exposure, as has been pointed out by Leber and others, are mostly monocular; and rheumatism, perhaps upon insufficient evidence, has been cited as the cause. Gowers,[1] writing upon this point, says: "Neuro-retinitis has been loosely ascribed to rheumatism, but only on the ground that it has sometimes appeared to be due to cold." Rheumatic inflammation at the back of the orbit, however, according to the same author, may damage the optic nerve. Michel,[2] commenting upon a reported case of acute, peripheral retro-bulbar neuritis, remarks that he has never observed a "rheumatic" neuritis, and he considers the assertion of such as a mark of ignorance of the causes especially operative in the production of inflammation of the optic nerve.

Hansell[1] thinks "that a true rheumatic inflammation of the fibrous coat of the nerve between the optic foramen and the sclerotic" quite possible, but owing to the infrequent opportunity for section and examination admits that "our pathology is, at best, speculative." The central scotoma which existed in this and similar cases denotes an affection of the sheath of the nerve extending into its substance, not, as Hirschberg remarks, as would have been supposed before the macular fibres were discovered, a central inflammation extending outward. The prognosis depends to a certain extent upon the site of the lesion, and the termination may be favorable, as in the case reported, or a permanent atrophy of the disk may result. Hirschberg,[2] in his cases of primary optic neuritis, has found usually that the second eye is attacked; the interval may be days, or weeks, or months. Three of his cases illustrate this fact A woman, forty-two years old, suddenly lost the sight of the right eye; in six days from the beginning of the attack this was well, but the left eye was attacked and optic neuritis developed; in three weeks recovery had taken place and the fundi were normal. In a second case a woman, twenty years old, had slight temporary loss of vision in the right eye three weeks before coming under observation for loss of vision in the left, which came on eight days before. Four months later she came with the right eye similarly affected, while the left had practically recovered. A third instance was that of a peasant girl, seventeen years old, who had her right eye attacked in 1878; she recovered, and in 1884 had her left eye attacked, and also recovered from this.

The treatment has already been discussed. Leeching of the temple, followed by blisters, diaphoresis, together with the salicylates and iodide of potash, yield the best results. Improvement may take place before the remedies have time to take effect.

—The *Medical Press and Circular*, Oct. 17, 1888, says that a manufactory has been started in Italy for the manufacture of a culinary oil from grape pips. A hundred pounds of the seeds yield about five pounds of a clear yellow oil.

THE SIGNAL SERVICE AND THE PHYSICIAN.

BY G. WALTER BARR, M.D.,
BRIDGEPORT, ILLINOIS.

Rheumatism and diseases of like character which have variations in symptoms in accordance with changes in barometric pressure, have been noticed for a long time; but the relation existing between that combination of temperature, barometric pressure, moisture, condensing point, wind, *et cetera*, which we call the "weather," and that combination of symptoms which leads us to speak of a patient as better or worse has never been fully worked out. I recollect hearing a celebrated gynecologist advise the postponement of serious operations when the wind is east, and have profited by the advice to the extent that my surgical operations are, whenever this is possible, performed in bright, clear weather. Walking patients often ask permission to make journeys, and patients with lung disease ask questions in the answer to which the weather is an important factor. Weather lore should not be left to old women and to men with goosebones or moon tables.

The source of the most accurate meteorological knowledge at present is the Signal Service of the United States Army. I have been for some time in the habit of watching the service here and allowing its predictions to influence my treatment of patients. The results have been such as to incite me to call the attention of the profession to the benefits of the practice.

Should a patient have any fever with the convenient prefix "typho-," a low barometer and an east wind will make him worse, unless their effects are overcome. The day before the beginning of a week's rain is a bad time to amputate a thigh or perform a laparotomy. In the back-country districts I have often amazed the visiting cohorts by ordering, on a balmy day, window-panes put in and crannies stopped, "because it will get cold about ten o'clock to-night." Only a country doctor, who is laying up ninety per cent of his treasure in heaven on the endowment plan, can appreciate the value of knowing when a cold wave is coming down on his scantily-clothed, miserably-housed sick.

As to the value of the Signal Service predictions, each man must collect his own data of verifications and not believe what his political organ says about them. Actual, careful records kept by me here for two years show a verification in over ninety per cent. of the cases, and that five per cent. more of the whole could be correctly predicted by a local observer. It seems to be difficult to make people understand what the predictions mean, and more difficult still to get them to make careful notations each day of weather and temperature variations. It does not do to follow blindly the "Indications," but local conditions and effects based on experience must become factors in the prediction of the weather. With a good vane and thermometer, and a little diagnostic skill, the Signal Service enables us to predict meteorological conditions about as correctly as the text-books enable us to diagnosticate pathological states. The weather influences prognosis and should influence treatment, and the truly scientific physician may well give it some attention.

SOCIETY REPORTS.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting, October 18, 1888.

The President, A. JACOBI, M.D., in the chair.

DR. M. ALLEN STARR read a paper on

Apraxia and Aphasia; Their Varieties and the Method of Detecting Each,

in which he said that some of the symptoms of aphasia are not recognized by the patient, while his condition prevents him from describing others to the physician. It is well, therefore, to call attention to the proper manner of examining patients who present one of the most interesting of all local symptoms, namely, aphasia. He said he ventured upon this task because of the recent discovery of defective thought and memory associated with aphasia, a condition which has been named "apraxia."

Speech disturbance, Dr. Starr said, is divided into sensory and motor aphasia. The memory of the sound of a word as spoken, the memory of its appearance when written, and the memory of the muscular movements necessary to write or pronounce it, are known to be distinct from one another and yet to be associated. The loss of these memories is termed respectively, word-deafness, word-blindness, and agraphia, and when it exists there is impairment of the word-image. A word, he said, is simply employed to express thought, and thought

precedes language. The word added to the mental image of a thing, which in the case of a pen has size, shape, and thickness and conveys the idea of writing, makes the conception communicable to others, but it is not essential to the idea. In a diagram displayed by Dr. Starr, of which a bell was the concept, there were seven circles connected with one another, three of which, representing auditory memory, tactile memory, and visual memory, have to do with the idea; while the other four, word-seeing-memory, word-hearing-memory, word-reading-memory and word-writing-memory, have to do with the use of language. Each or all the sensory organs, when called into play, may fail to arouse an intelligent conception of an object; to express this failure the term apraxia is employed. Apraxia is frequently associated with aphasia, and may lay at the base of it. Hence it should be determined by various tests, whether or not the person gives evidence of recognition. He should be watched by his friends to learn if he still has the same appreciation of his food, if he continues to admire pictures, flowers, etc., and if he recognizes perfumes—in short, if bodies any longer awaken ideas in the mind as they did previous to the aphasic attack. Certain varieties of apraxia, as those of word-blindness and word-deafness, have been studied, while others have received little attention. Investigation of the power to recognize and name objects by the touch, taste, and smell would be interesting, but have not yet been undertaken. Of the cases of apraxia which Dr. Starr has been able to collect, the lesion has always been found in the left hemisphere in right-handed persons and in the right hemisphere in left-handed persons; in other words, in the same hemisphere which is the seat of the lesion which produced the aphasia.

Apraxia has as many varieties as there are organs of sensation, and in all cases of aphasia examination should be made for apraxia. It is well known, he said, that lesions of the right hemisphere in right-handed persons, and of the left hemisphere in left-handed persons, do not produce aphasia; and it seems also that memory of objects must be located on the same side of the brain as that which produces speech. In all the cases of psychical blindness which Dr. Starr has been able to collect, the lesion lay in the angular gyrus; in cases of word-deafness it lay in the temporal convolution, and when both word-blindness and word-deafness existed there was a lesion of both the angular gyrus and temporal convolution. Dr. Starr's collection contains forty-five cases, and is larger than any other yet made. The histories of two occurring in his own practice, illustrative of aphasia in which there was word-blindness and word-deafness, were read. Every patient should be tested, he said, as to his power to write voluntarily, to copy, and to write from dictation. Some patients can figure when they have lost power to read and write.

The complete severance of association fibres may, he said, cause disturbance of the mental image. Four cases of deep-seated lesion in the occipital lobe underneath the cortex have been found at death in such a position as inevitably to affect the associated fibres passing to the angular gyrus. If one association tract be impaired, others may remain open, and before saying that the memory picture is lost one should test all channels leading to it. Such acts as reading aloud, writing at dictation, and copying involve association fibres.

In his first case, word-blindness and word-deafness were present in about equal degree. The diagnosis was that of embolism of the terminal branches of the left Sylvian artery. There was no loss of power to write words. In the second case there was also word-deafness and word-blindness, no motor aphasia, no agraphia, but marked impairment of understanding what the patient heard and read. Hearing and sight were normal. The patient did not recover from his sensory aphasia, but died of acute encephalitis.

Dr. W. R. Birdsall remarked that Dr. Starr's reference to disturbance of the musical faculty in some cases of aphasia reminded him of his first case, that of a violinist, who lost power to speak but retained power to read musical notes and to play the violin. He thought Dr. Starr's diagram of the list of cases showed the superior value of pathological observations over physiological experimentation in cerebral localization.

Dr. E. D. Fisher said he felt that it was a question whether or not so-called cases of sensory aphasia could be attributed to a definite local lesion, for the location of the general intelligence being unknown (it might even rest in the entire cortex) it was difficult to say the cortex was not involved. He could not understand how, with our present knowledge, we could say positively that the supposed centers in the cortex were alone involved, and that the symptoms were not due to a lesion in the white matter or connecting fibres. This difficulty was not

easily solved when it concerned sensory lesions, but it was less difficult in motor aphasia

The PRESIDENT said he could recognize the difficulties in diagnosis pointed out by Dr. Fisher. A number of cases were on record in which the symptoms pointed to a definite local brain-lesion while the autopsy showed an extensive lesion, and the contrary.

DR. PUTNAM JACOBI thought the diagram was incomplete in picturing only memory centers of nouns or verbal expressions, and leaving out of account the higher center for the idea.

DR. A. H. SMITH, when studying a case of aphasia, thought the condition present might be described as "psychical incoördination."

DR. STARR, in closing the discussion, said that he regarded no one center as necessary for the concept "bell," which was the object figured in the diagram; that the image was made complete by the auditory, visual, and tactile centers, and that any disturbance of these, or of their connecting tracts, would make the concept imperfect or destroy it completely. But if there was one center for the idea, a lesion in that limited area, not involving the others mentioned, should entirely destroy the mental image; but no patholog ical findings went to support such a view.

FOREIGN CORRESPONDENCE.

LETTER FROM BERLIN.

(FROM OUR SPECIAL CORRESPONDENT.)

Inhalation of Heated Dry Air in Consumption.—Effects of Heated Damp Air in Consumption.

BERLIN, Oct. 12, 1888.

The chase of medical men after satisfactory treatment of tuberculosis has well-nigh assumed the character of a craze. National vanity, besides, seems to have spurred the German profession not to be outdone by the French clinicians, who, like Bergeon, Dujardin-Beaumetz and Germain Sée have recently surprised the professional world by their wonderful "cures" of consumption. But by some strange coincidence "the Yankees" have again asserted their traditional prerogative in the way of discovery. Dr. Weigert, of Berlin, who was the first to hit upon a new and successful method of treating consumption, turns out to be an American. But, as such merit and precedence could not very well be allowed to an American physician, Dr. Halter has presented his claims to priority. The new principle of treatment consists in the *inhalation of heated, dry air.* Dr. Weigert appears to have sustained his claims, and the most prominent secular journals have finally taken his part. As the result of this an article appeared in some journal, in which Dr. Weigert's assumption of addressing the Berlin physicians by the epithet of "colleagues" was stigmatized, Dr. Weigert being merely a "Philadelphia doctor." To be a Philadelphia doctor, it needs to be explained, means in Germany to be an impostor and a swindler who has simply bought his diploma. There is actually scarcely a week passing, but some paper publishes an article against some alleged "Philadelphia doctor." To rectify this matter your correspondent has transmitted to the *Berliner Tageblatt* a polite note explaining that the "Philadelphia University" *alias* Buchanan & Co., has long ago ceased to exist, and that Philadelphia is justly considered as the centre of American medicine, having three regular medical schools of first-class standing, besides a Woman's College, a Homœopathic School, and a Polyclinic. Singularly enough no notice whatever was taken of this communication. Your correspondent, however, will not be satisfied until both the German profession and the public are in possession of the truth concerning medical affairs in Philadelphia. It will be of interest to Philadelphians to learn that Prof. Da Costa's book on diagnosis is the official text-book at the Royal University of Berlin, and that the names of Gross, Mitchell and of several other Philadelphia physicians are household words among the German profession.

The favorable results obtained by Dr. Weigert with inhalations of superheated dry air have led Dr. Krull, a practitioner of Güstrow, Mecklenburg, to try the effects of *damp heated air in consumption.* His experiments, however, date back two years and a half. Krull has just published a paper on the cure of consumption by inhalations of damp, warm air, of a constant temperature. The author is quite right in saying that the sanguine anticipations in regard to all antibacillary methods of treating tuberculosis have been a failure. Even Sommerbrodt's creasote treatment has not proved a success. Krull's plan is to abandon wholly the antiparasitic principle and to return to old principles by new means. The basis of his

treatment is the view that a defective nutrition of the lungs favors the admission and development of pathogenic bacteria, and that by directly increasing the blood supply and vital energy of the lungs, the local powers of resistance and recuperation can be considerably increased. This desideratum Krull attains by means of inhalations of sterilized, damp, atmospheric air, the temperature of which can be regulated by mechanical devices. The result of introducing into the lungs damp air of a higher temperature than that of the body is a vascular dilatation, and the passage of a greater quantity of blood through the lungs without concomitant cardiac excitation. As damp air heated to a definite limited degree does not decrease the elasticity of the blood-vessels, each cardiac contraction carries off the quantity of blood admitted previously to the part. It is evident that through this increased admission and expulsion of blood a greater quantity of it will be propelled into the capillaries of the lungs, and that an augmented oxidation of blood will take place in a given time. Simultaneously, the discharge of carbonic acid gas is increased and the processes of pulmonary nutrition and general tissue-change are stimulated. Thus it is possible to check, even in an already affected lung, the progress of the affection, by rendering the still healthy part more capable of resisting the propagation of the tubercle bacillus. Restoration may then take place, either by resorption or by vascular new formation. This recuperative tendency of the lungs is also favored by the water, which in the form of vapor has entered the lungs simultaneously with the hot air and tends to soften and expel cheesy deposits. Possibly the hot air exercises also a deleterious influence on the development of the bacillus. Strange to say, as Krull's observations have shown, the danger of pulmonary hemorrhage is not only not increased by these hot inhalations, but they, by equalizing dangerous centres of blood-stagnation, actually diminish it. Krull has constructed an apparatus for the convenient inhalation of sterilized, damp, hot air. In using it, the patient rests his arms in arm-slings and applies his mouth to a mouth-piece attached to the apparatus, compressing at the same time with his finger the alæ of the nose.

Krull has also experimented with these inhalations on a large number of healthy and tubercular subjects, and has obtained such favorable results as to attract the attention of all practitioners of medicine to his treatment. The inhalations produce no tendency to cough, are pleasant and never create a laryngeal or bronchial catarrh. Cardiac excitation was also never observed. A healthy person gained under this treatment two pounds a week. A tubercular woman, 18 years old, had at the end of Krull's treatment gained twenty-six pounds in all. The best results have been obtained with air heated to 103° F., and by one inhalation daily between 7 and 8 A.M. or 5 and 6 P.M., and lasting thirty or forty minutes. If syphilis or albuminuria is present, Krull's treatment is useless. The most satisfactory results, as would be expected, are obtained in the very beginning of tuberculosis, even of an inherited character. It is to be hoped that more extended clinical trials of Krull's treatment will establish their therapeutic worth.

PERISCOPE.

Saccharine in the Adulteration of Food.

MM. Brouardel, Pouchet and Ogier have been investigating the employment of saccharine as an adulterant of food. They conclude that (1) saccharine is not a food and cannot replace sugar; (2) its employment in the food suspends or retards the transformation of starchy and albuminous substances in the digestive tube; (3) substances containing it, therefore, cause great disturbance of digestion, and are calculated to multiply dyspeptic troubles; (4) its employment in food is still too recent to enable one to determine with precision the consequences of its daily use; but, for the present, it is established that its use has an injurious influence upon digestion, and that the committee is right in concluding that saccharine and different preparations of it ought to be prohibited from food.—*Bulletin Médical*, August 18, 1888.

Reaction of Urine Containing Salicylic Acid.

Pollatschek (*Wiener med. Wochenschrift*, No. 21, 1888) directs attention to the strong reducing property of urine passed after the use of salicylic acid, when this urine is heated with Fehling's solution; it causes a deceptive resemblance to the sugar reaction. This reducing property of salicylic acid was first discovered by Fleischer.—*Centralblatt f. d. med. Wissenschaften*, September 1, 1888.

Case of Poisoning with Antifebrine.

J. Meyer (*Therapeutische Monatshefte*, No. 5, 1888) reports a case of poisoning with antifebrine. The subject was a man 38 years old, disposed to attacks of catarrhal bronchitis, who was at the time suffering with an attack of migraine. A druggist of Berlin gave him two doses of antifebrine, each containing thirty grains, which the patient took within twenty-four hours. The first dose was well borne, but about fifteen minutes after taking the second dose, symptoms of poisoning manifested themselves. The latter consisted in cold sweat, feeling of great prostration, anguish, palpitations, very small and frequent pulse. By and bye a slight cyanosis spread over the face, lips and hands.

The patient was given a cup of black coffee, followed by castor oil; sinapisms also were applied. The cyanosis gradually disappeared. The other toxic symptoms subsided but slowly, and for several hours the patient felt dejected.—*Gazette Médicale*, August 25, 1888.

Uræmic Convulsions Following Post-Scarlatinal Nephritis.

Dr. James Mason, in a communication to the *Lancet*, July 14, 1888, says that although the following case presents little novelty either in its clinical features or in the treatment adopted, still a summary of its salient points may not be entirely without profit. It illustrates, among other things, he says, that even when the greatest care is taken post-scarlatinal dropsy may occur, and also that even in what are apparently most hopeless cases recovery may take place. It is further interesting, he says, as illustrating how careful one ought to be in adopting the *post hoc, ergo propter hoc* method of deduction.

The patient, a boy about eight years of age, suffered, along with the other members of a large family, from scarlet fever. Fourteen days after the rash had disappeared œdema of the eyelids and hands was observed. There was a considerable quantity of blood present in his urine, for which hazeline (a distillate from hamamelis Virginica), among other drugs, was tried, but without obvious benefit. The usual fomentations were applied, and he had several hot baths; but on the fourth day after the appearance of the œdema he was seized with a convulsive fit, the clonic spasm being, however, entirely confined to the left side. On being called, Dr. Mason at once gave him a hot blanket bath, and injected an eighth of a grain of pilocarpine over the deltoid. Although free perspiration soon followed these agents, the stertor seemed to increase and the coma to deepen. After consultation it was decided to try venesection. The median basilic vein was opened, but so altered was the blood and so weak was the circulation that only a few drops of thick treacly fluid escaped. After trying various ineffectual means to increase the flow, the incision was covered up and the boy was left to die. Next morning, however, he was laughing and chatting with his brothers, who were convalescing from scarlet fever, and in three weeks more he was fit to go to the seaside.

Dr. Mason remarks that had he obtained a free flow of blood from the boy's arm, he certainly would have been inclined to credit the venesection with the cure, and, reasoning from that, would have been more inclined to adopt that practice in any similar case. The moral to be drawn is obvious.

Purgative Action of the Galvanic Current.

Some time ago, Dr. Schildbach published a paper containing the following statements, based on some experiments of his own: 1 A moderately strong galvanic current (cathode in the rectum, anode on the abdomen) gives rise to vivid peristaltic movements of the intestines. 2. A sitting of 10 or 15 minutes is followed by stools in one or two hours. To verify Schildbach's assertions, Dr. A. Chelmonski, a Polish practitioner, has recently undertaken a series of experiments in two healthy persons and in eight patients with habitual constipation. His results, as described in his communication in the Warsaw *Gazeta Lekarska* (1888, No. 19), may be condensed thus: 1. In 9 out of 10 cases, the sitting was followed by defecation in from fifty minutes to twelve hours, the stools being of a gruel-like consistence. 2. In 4 of the 9 cases, the stools were followed in two hours by diarrhœa. 3. In 3 of the 10 cases, during the electrization, there were observed facial pallor, extreme weakness of the pulse, perspiration, giddiness, and aural noises; while in one case a true syncope supervened. Dr. Chelmonski's general conclusions are to the effect that the laxative effects of the current are not so rapid and satisfactory as Schildbach alleges, and that the current sometimes manifests an unpleasant influence both on the intestine and heart.

Syphilitic Ulcer of Anus.

Dr. Mark F. Patten, of San Buenaventura, Cal., reports an interesting case of this affection in the *Pacific Med. and Surg. Journal*, August, 1888. A young man, 17 years old, consulted him February 9, 1888, with the following history: Five weeks previous, while in Los Angeles, he was obliged, on account of the scarcity of lodgings, to occupy a bed with a man who was a stranger to him. In the middle of the night he was awakened by his bed-fellow, who was in the act of committing an assault upon him. On his resisting and making an outcry, the man choked him, relieved him of his watch and money, and then decamped. Three weeks after this a sore appeared at his anus, which became exceedingly painful, and it was for this that he consulted Dr. Patten.

On examination, the latter found a large ulcer involving one-half the circumference of the anus, with edges well defined and somewhat indurated. It was very sensitive to touch, and defecation caused great pain. There was also slight enlargement of one of the inguinal glands. It was a question whether this was a case of syphilis or not, and if it were not for the rapid growth of the anal ulcer and the increasing painfulness of defecation, Dr. Patten would have waited for secondary symptoms to become manifest before resorting to specific treatment. He, however, thought it best to place him on a mercurial (bichloride) course at once. In one week, he says, the anal ulcer was entirely healed. The mercurial did not retard or prevent the development of secondary symptoms, as on the forty-seventh day after exposure to infection his body became covered with a typical syphilitic roseola.

Influence of Antipyretics upon the Retention of Glycogen.

MM. Lépine and Porteret have been studying the effect of antipyretics upon the glycogenic function, and have already announced that they retard the transformation into sugar of the hepatic glycogen. In subsequent investigations (*Gazette Hebdomadaire*, August 24, 1888) they have sought to determine the influence exercised by antipyrine and antifebrine upon the proportions of glycogen. After having described their method of procedure with the purpose of eliminating error, and stated that it is indispensable in a study of this kind that the animals experimented upon should be of the same litter, differing little in weight and in the same condition of nutrition, they announce the results they have obtained. Their conclusion is that animals poisoned with antipyrine and antifebrine have, in comparison with healthy animals taken as tests, an excess of muscular glycogen of 28 to 20 per hundred—a fact that is not without importance as bearing upon the theory of the action of antipyretics.

Treatment of Ulcers of the Cornea.

At the meeting of the American Ophthalmological Society, September 19, 1888, Dr. P. A. Callan, of New York, read a paper on the treatment of ulcers of the cornea. Ulcers occurred in young persons, and were often phlyctenulæ of the cornea, in which neglect and lid friction had caused absorption and an ulcer. A salve of the yellow oxide of mercury should be placed between the lids once daily; atropine and cocaine should be used, if necessary; and also tonics and open-air exercise, regulated diet and airy sleeping-quarters, smoked glasses, but no bandages or dark room. For ulcers due to conjunctivitis, that affection should be treated. In gonorrhœal ophthalmia, ophthalmia neonatorum, or granular conjunctivitis, efforts should be redoubled when the cornea is threatened—cutting the canthus, applying leeches or ice compresses, etc. Referring especially to ulcers without apparent cause, due to some constitutional trouble—malaria, syphilis, etc.—the author said that the constitutional remedy should be employed, and, under cocaine, the ulcer cleansed with a piece of absorbent cotton wrapped on a holder. Then, with another piece of absorbent cotton, it should be swabbed with a two-grain solution of nitrate of silver, leaving no part of the ulcer untouched. This might have to be repeated two or three times in as many days. The eye should be bathed with hot water (120° to 130° F.), for half an hour, three times daily. If much corneal irritation existed, the cornea should be bathed with a boric acid solution; then atropine and cocaine used, and the eye kept bandaged. The point to be aimed at is to get a clean wound, and this is obtained better and more safely, he said, by use of the nitrate-of-silver solution than by any other means known to him. Besides clearing the ulcer, the nitrate of silver stimulated repair.

Dr. W. F. Mittendorf, of New York, thought the electro-cautery should be used on sluggish ulcers and on those inclined to spread rapidly, with sloughing edges.—*N. Y. Med. Journal*, October 6, 1888.

Case of Dextrocardia.

The *British Med. Journal*, July 7, 1888, says that at a meeting of the "Ateneo" of Brescia, Italy, June 3, Dr. Emanuele Anselmi showed a case of dextrocardia in a young man. The right side of the thorax was far more prominent than the left, and the muscles covering it were much more developed. The apex-beat was close to the sternal end of the fifth intercostal space of the right side. The relative position of the ventricles was unchanged, and the great vessels were not transposed; the heart in fact was as if it had been forcibly pushed over to the right, so that being unable to move downward on account of the liver, it had gone forward, bulging out the ribs to make room for itself. The great vessels appeared to have undergone a twist, or rather a more marked curve than usual, for the blood reached the radial arteries on both sides after a longer interval than the normal one, and the second sound of the heart was somewhat unnaturally strong. The patient had never had any symptoms referable to the heart except after excessive physical exertion, and physical examination failed to reveal anything wrong either in that organ or in the lungs. Dr. Anselmi was inclined, in the absence of any history of disease which might have caused dislocation of the heart, to attribute the malposition to some inflammatory affection occurring during the embryonic period.

Microkinesis.

A paper by Dr. Francis Warner, on muscular movements in man and their evolution in the infant, was read at the meeting of the Royal Society, June 12. In the newborn infant continual movement may be observed in all parts during the waking state; these spontaneous movements, to which Dr. Warner proposes to apply the term "microkinesis," cannot be stopped by external stimuli. This condition becomes gradually modified during the growth and development of the child, and the movements are gradually more and more controlled by external stimuli, while the phenomena termed memory and imitation are evolved. The paper also contained a study of the modes of action of nerve-centres in adult age, and it was suggested that when a co-ordinated movement follows a slight stimulus, temporary unions are produced among the centres, and that the brain-action corresponding to thought is the formation of functional union among cells; the outcome of such functional unions is seen in the movements which express the thought. Dr. Warner described a number of special postures and movements associated with certain states of the brain, and in fact affording physical signs by which those states might be recognized.—*British Med. Journal*, June 30, 1888.

Medicines Excreted by the Bile.

Prevost and Binet (*Revue méd. de la Suisse Romande*, May 20, 1888, made biliary fistulæ in two dogs, and investigated experimentally the action of drugs upon the secretion of bile, and their excretion by the bile. Their results are as follows: 1. Although fat is not decomposed on account of the absence of bile from the intestinal canal, the animals experimented on continued to be well nourished. 2. The quantity of bile secreted increases considerably in proportion to the food ingested, especially when the latter is rich in peptones, less when it is rich in fat. Ingestion of water increases the secretion of bile if the quantity of water exceeds seven fluid ounces. Agents which increase the secretion of bile are: gall itself in its natural state or in the form of a glycerine extract, bile salts, urea, oil of turpentine, terpinol, potash, benzoin, salicylate of soda, salol, muscarin. The following increase the secretion only in an insignificant degree: bicarbonate of soda, sulphate of soda, chloride of sodium, Carlsbad salts, propylamine, antipyrine, aloes, cathartic acid, rhubarb, hydrastis Canadensis, ipecacuanha. The secretion of bile is lessened by iodide of potash, calomel, iron, copper, atropine, strychnine. Phosphate of sodium, bromide of potash, chloride of lithium, corrosive sublimate, arseniate of sodium, alcohol, ether, glycerine, caffeine, pilocarpine, kairine, cytisus, senna, colombo—were without appreciable influence upon the secretion.

Of the agents ingested the following could be detected in the bile that escaped through the fistula: turpentine, terpine, terpinol; salicylic acid (also found after salol was given), bromide and iodide of potash, potash, arsenic; iron, lead, mercury (these three in traces); caffeine, fuchsine, cochineal, finally gall itself. The gall of dogs becomes of a more greenish hue after ox gall has been given, and smells then like ox gall. Moreover, glycocholic acid can then be detected in dog's gall, although this is never found normally in the latter, but is always met with in ox gall. The following agents were not detectable in the bile: antipyrine, kairine, hippuric acid, strychnine, copper, lithium, urea.—*Wiener med. Presse*, July 29, 1888.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MEDICAL LEGISLATION IN TUNIS.

The attention of the medical profession in the United States has of late been strongly directed, in the State and National Societies, to the necessity for the adoption of wise and uniform laws for the regulation of the practice of medicine. For this reason we think it may be useful to give an epitome of the laws in regard to this subject which have recently been promulgated in Tunis.

These laws make the following provisions:—

Since July 15, 1888, no person can practice medicine, in any of its branches, in Tunis except under the following conditions: Every person intending to practice medicine must, within one month of fixing his or her residence, declare this intention, in writing, to the civil "controller," and deposit a diploma entitling him or her to practice in the country in which it was issued. This diploma will be examined, and, if found correct, will be returned, with a certificate authorizing its possessor to practice. In case of removal from one district to another this certificate must be registered with the local "controller," within one month.

The names of all persons entitled to practice are to be published at the beginning of each year in the *Journal Officiel Tunisien.* Persons authorized to practice must do so only in the districts to which their certificates apply.

No person may practice medicine and pharmacy at the same time; but any physician may sell medicines if he resides in a district in which there is no authorized pharmacy.

Every person is regarded as practicing medicine who habitually gives advice, or professes to give advice, for a salary or gratuity, or as to a method of treatment, or the use of any substance which he represents as capable of curing disease, or who practices manipulations or operations having the same object, or who practices midwifery.

Every violation of this law is to be punished with a fine of from ten dollars to one hundred dollars. If the violation is accompanied with usurpation of a title, the fine ranges from twenty dollars to two hundred dollars. If the offense is repeated, the fine is doubled and an imprisonment, not exceeding three months may be added. Prosecutions may be instituted by official action, or at the request of any person authorized to practice, or by any medical society, and the latter have the right in any case to *bring a civil action for damages against the offender.*

The only persons exempt from the provisions of the preceding laws are, 1. persons who have already practiced for five years in Tunis, and *who can show that they have studied medicine for at least three years in a*

medical school. Every year of such study in excess of three is to be counted as equal to a year of practice in Tunis.

2. Natives at least sixty years old, who have practiced medicine for twenty years, and those who are at present possessed of an "amra" from the Bey.

3. Natives who practice in places or tribes where there is no one possessing a legal title to practice.

4. Women now practicing midwifery: who may continue to do so, if they apply for permission within two months.

None of the persons thus exempt may practice any operation, except of minor surgery, nor may they be called as experts, or give medical certificates, or assume the title of "doctor," or any other which would lead to the belief that they have a certificate of authorization to practice. Women who practice midwifery may not perform any obstetrical operation or prescribe medicines, and in case of difficult or protracted labor they must summon a legalized practitioner.

The rights conferred by this exemption may be revoked for good cause and shall be revoked in case of a conviction for practicing illegally.

In studying the provisions of the law we have just epitomized, our readers will probably be struck with the high standard which they set up for the practice of medicine in Tunis, and they will perhaps think that this standard is hardly attainable in our country. This may be the case; but we hope that they may furnish some useful suggestions to those who hope to influence medical legislation in America, and that their manifest consideration for the rights of the natives, as against the claims of those who may wish to make a living by practicing medicine upon them, may not be overlooked.

We think our legislators might do worse than to adopt the provisions of the Tunis law bodily, and we sincerely hope they may at least come near them when they act upon this important subject.

WHOLESOME RECREATION.

Not many weeks ago Dr. J. T. Rothrock, Professor of Botany in the University of Pennsylvania, returned from a visit to the coast of Maine, in which he had carried out with great success an idea of his for making a summer vacation furnish to a number of boys recreation, instruction and improved health. Most of the time was given to sailing and fishing. A considerable portion was spent on an island, where the boys could not indulge in long walks, but where they had abundance of opportunity for moderate muscular exercise. In the evenings they had lectures upon such emergencies as may occur at any time among boys—being shown how to resuscitate a boy taken out of the water insensible, how to treat a case of sunstroke, how to get a boy home with a broken limb, how to stop the bleeding from a cut artery, how to reduce certain dislocations, how to apply bandages, etc. Commencing with the head, they went over the entire body, being taught how to apply these lessons as occasion might arise. The leading idea was to make the excursion a vacation and not a school, hence all instruction was confined to the evening. Whilst its headquarters were on the island, the party cruised as far north as Mount Desert, making in all a cruise of about ten days. The only supervision that was exercised over the boys was simply enough to keep them out of harm's way. As might be expected from Dr. Rothrock's chief line of study, rather extensive collections of the flora of the region visited were made, and interesting matters of local history and natural science were also studied.

We do not mention this enterprise simply to praise it, but rather to commend it to imitation. Under a judicious leader an excursion of this kind could not fail to be of service every way, to young people, or indeed to people of any age; and what has been done by Dr. Rothrock may furnish a suggestion to many of our readers which they could carry out with the greatest

pleasure and advantage to themselves and those who enjoy their professional care.

THE CLAIMS OF THE BODY.

Now that the schools have opened again, it may be worth while to call the attention of those who govern them to the opinions of medical men as to the way in which school children should be treated. It will hardly be claimed that physicians are indifferent to the mental development of the rising generation, and yet they are continually found protesting against the way in which schools are conducted. The number of hours during which children in the public schools of the United States are compelled, or incited, to study are too many; and medical men are practically unanimous in the opinion that they should be curtailed.

Dr. Hammond, of New York, has recently called attention to the error of overloading the minds of school children, and repeated certain arguments which have been advanced over and over again against the system of cramming to which, in spite of many praiseworthy efforts of wise school directors, a large number of scholars are subjected.

But we would go further than he does, and urge the deliberate and systematic cultivation of physical health in all well-ordered schools. In our day there is a wholesome tendency, all over the civilized world, to regard mental culture less exclusively than our fathers regarded it, and to attach more importance to the needs of the body than they did. But even yet we may improve, and perhaps some day we shall reach the point when the possession of a healthy body shall be recognized as indispensable to a perfectly healthy mind, and when it shall be fully understood that a healthy body with a moderate education is infinitely preferable, for the individual and for the race, to a highly cultivated intellect with a wretched physique. This may sound to some like the praise of purely animal excellence; but we believe that a sensible view of the matter will inevitably lead to the conclusion that the mental and moral prospects of the human race will be improved with every improvement of its physical powers, and that the outlook for the future is brighter now than it ever was, because medical men are asserting the claims of the body for thoughtful consideration, and the community seems to be taking their teachings to heart. We have no fear that the minds of those who follow us will be neglected, and it is encouraging to find that their bodies are more and more regarded as worthy of attention.

A practical application of these thoughts may be suggested, namely, that physical education should be made a part of every organized system of general education. And we believe that this can be best done under the supervision of medical men. Every school in America should have the services of a physician, first, to examine the pupils in regard to their ability to pass through the prescribed curriculum without injury to their health, and, second, to direct the measures designed for the development of their physical strength.

Such an adviser should especially superintend any system of gymnastics which may be adopted, and see that the scholars are encouraged to indulge in recreations and sports which strengthen the vital functions. He should be a sort of cultivated trainer, to make those under his care strong men and women physically, and to supplement from his side the endeavors of the teacher to develop their mental faculties. This combination is, in our opinion, necessary for an ideal school, and to this we sincerely wish that all our schools may come.

MEDICAL POLICE SERVICE IN PHILADELPHIA.

Dr. Thomas H. Andrews, Police Surgeon of Philadelphia, has recently secured the adoption of regulations which will very much ameliorate the lot of those who come under the care of the police in conditions of sickness or injury, of body or mind. Formerly the division of authority in the

government of the city led to delays in the treatment of this class of unfortunates which were always troublesome and sometimes disastrous. Under the present form of government, it has been possible to make the different city departments work harmoniously and to reduce to the shortest possible limit the time necessary to transfer a sick, or insane, or injured person to the proper hospital.

At the suggestion of Dr. Andrews, Mayor Fitler has authorized the issuing of orders requiring the immediate reception at the Philadelphia Hospital of any patient sent there by the police surgeon's direction. Chief of Police Lamon has given instructions to the lieutenants, and Dr. Andrews has issued a circular letter to the district surgeons notifying them that when any sick or insane person, with no one to take care of him or her, was brought to the station house, the lieutenant would give notice immediately. This takes from the lieutenant, and assigns to the district surgeon, the duty of judging whether a "prisoner" is intoxicated or sick. The district physicians are to answer the summons at once, and if, in their judgment the patient needs hospital treatment, he is to be sent to the Philadelphia Almshouse without delay.

These arrangements have so far worked admirably; they have relieved the police of much responsibility and have proved of great advantage to those who come under their care.

Both Dr. Andrews and the Mayor of Philadelphia are to be congratulated upon the carrying out of this much needed reform, and we trust it may prompt the authorities of other cities to adopt similar humane and intelligent measures of medical police service.

—There were 23 new cases and 2 deaths from yellow fever in Jacksonville, Fla., Friday, October 26. The total number of cases up to that date has been 3997, and the total number of deaths, 341; a mortality of about 8¾ per cent.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A SYSTEM OF OBSTETRICS BY AMERICAN AUTHORS. Edited by Barton Cooke Hirst, M.D., Associate Professor of Obstetrics in the University of Pennsylvania, Obstetrician to the Philadelphia and Maternity Hospitals, etc. Vol. I. Illustrated. One colored plate; 309 engravings on wood. 8vo., pp. 807. Philadelphia: Lea Brothers & Co., 1888.

This work is issued in connection with the System of Gynecology by American Authors, and is intended to furnish a complete exposition of the science of obstetrics, and embody the knowledge of well-recognized authorities in the profession in this country, whose teaching is especially adapted to our own conditions and surroundings. Volume one is made up of eight papers by different writers. The distinguished reputation of its contributors will insure the work a wide distribution in this country; and as the most comprehensive American treatise upon obstetrics, it must be sought for abroad as containing distinctively American views upon the art as well as upon the science of obstetrics.

Engelmann, of St. Louis, contributes the introductory paper, on the history of obstetrics. This contribution is of the same high order that has characterized the other writings of this author. No inconsiderable part of this paper is the result of original investigations concerning the obstetric customs and practice among primitive peoples. Toward the end of the article will be found convincing evidence of the great advances which have been made in scientific obstetrics, and of the benefits which have accrued to mankind from the application of scientific knowledge to the obstetric art. This is especially true of antiseptic midwifery. This section will be read with interest and profit by all who are called upon to practice obstetrics. The Editor is to be commended for having selected a scientist—Martin, of Johns Hopkins—to write the chapter on the physiology and histology of ovulation, menstruation and fertilization, and the development of the embryo. The standing of the author affords ample surety of the intrinsic worth of the contribution. The Editor, Dr. Hirst, contributes the paper on the fœtus, its physiology and pathology, which is very much more complete than that usually found in works on obstetrics. Having signified our opinion of the article as a whole, we wish to refer particularly to one subject—the management of cases of abortion with retention of the placenta. Our author enters very fully into the status of this question, both from the scientific standpoint and from that of authorities. His advice in general is most excellent, and, in the opinion of the reviewer, is to be commended, especially in that he advises to use the finger in preference to any mere instrument to separate adherent placenta from the uterine wall. Immediately afterward, however, Simon's spoon-curette is recommended for the removal of the thickened decidua which remains after early abortions. Aside from the question of the necessity for the artificial removal of this tissue, the method here recommended is certainly dangerous, and is not in accord with the views of American obstetricians—not excluding those who believe in the "active treatment" of incomplete abortion, as distinguished from the "expectant treatment." While some, as Goodell, entirely reject the use of the

curette after abortion as inefficient, and at the same time dangerous, others, and perhaps a larger number, advise it under certain circumstances, but are at the same time emphatic in specifying the *dull* curette, perhaps of Thomas or Mundé; and they are equally outspoken in condemning the use of the sharp instrument, as being likely to cause injury, if not perforation of the uterus. Indeed, our author reports such a case as having occurred in Berlin, resulting in death to the victim, and imprisonment to the physician.

The chapter on the physiology and pathology of pregnancy, by Jaggard, embraces one hundred and fifty-six pages, and is one of the most complete and thoroughly satisfactory in the book, and indeed in any English work. It certainly reflects great credit upon its author, who is one of our younger obstetricians. The section on the physiological and clinical phenomena of natural labor, the conduct of labor, and the physiology and management of puerperal convalescence, is by Busey. The important and purely practical chapter, on the mechanism of labor, and the treatment of labor based on the mechanism, is contributed by Penrose. This author has the happy faculty of saying what he means in such a way that the reader cannot misunderstand him. The contribution is a clear exposition of the views of its distinguished author upon the subjects treated, and as such will be welcomed, not only by his many former students, but by the profession at large. However, in a work which aims to be exhaustive, the reader expects a full presentation of the subject, when theories conflict, and it is disappointing to be referred to other works for the desired information.

The chapter by Reeve on the use of anæsthetics in labor is a complete presentation of this subject. The author pronounces in favor of chloroform as *the* anæsthetic for use in labor, considering it to be as safe as any other, and far more manageable and pleasant. The Editor adds a section on the use of ether in obstetric practice, in which he advocates this agent as "most satisfactory to the obstetrician if used with skill and judgment." Being convinced of the superiority of chloroform, not only by the able presentation of the matter by Reeve, but also by practical experience with both agents, we cannot accept the latter statement—except in those rare instances in which it is desirable to push anæsthesia to the surgical degree. Parvin's erudite contribution on the anomalies of the forces in labor is the concluding section of the first volume. The many original illustrations, taken largely from specimens to be found in Philadelphia museums, are a feature of the book of no mean value. The work of the publishers could hardly be improved upon. Doubtless volume two will be equal in merit to volume one, and both will form an important addition to English obstetric literature.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

Moral and Criminal Responsibility. By P. Bryce, M.D., Tuskaloosa, Alabama. From the *Alienist and Neurologist*, July, 1888. 22 pages.

The Appendix Vermiformis, its Function, Pathology and Treatment. By Henry H. Smith, M.D., Philadelphia. The Diagnosis of Peri-cæcal Abscess, and its Treatment by Removal of the Appendix Vermiformis. By Thomas G. Morton, M.D., Philadelphia. From the *Journal of the Amer. Med. Association*, June 9 and 16, 1888. 44 pages.

—Dr. Bryce's paper on the moral responsibility of criminals is exceedingly interesting and instructive. He is so firm a believer in the controlling influence of hereditary tendencies and surrounding circumstances that he does not hesitate to say that criminal acts have no moral aspect whatever, so far as the criminal is concerned. At the same time he distinguishes between what is called moral responsibility and legal responsibility, holding that the State should restrain or punish criminals, as the occasion may demand, for the protection of society, and suggesting special methods and special judicial machinery for dealing with peculiar cases. His paper is full of interest and instruction, and while those who study it may not agree with all of his opinions, they cannot fail to find in it food for profitable reflections.

—This interesting pamphlet contains papers read by Drs. Smith and Morton before the Surgical Section at the last meeting of the American Medical Association. Dr. Smith's paper gives an admirable summary of the anatomy and physiology of the vermiform appendix, and of the pathological changes to which it is liable, together with a sketch of the symptoms of appendicitis and the treatment appropriate to it. The latter is brief but excellent, and places in a thoroughly scientific light the relative importance of medical and surgical treatment. An interesting feature of Dr. Smith's paper is the mention of writers and surgeons who long ago presented views in regard to the appendix and the treatment of its diseases which are apparently unfamiliar to many who write and speak about them nowadays, and which anticipated many opinions which are usually regarded as novel.

Dr. Morton's paper discusses the surgical treatment of peri-cæcal abscess, and advocates removal of the appendix when—as is often the case—this is dependent upon disease of the latter. Those of our readers who read the Reporter of January 7, 1888, have already an idea of Dr. Morton's views on this subject, which are more fully elaborated in the present paper.

To all of our readers we can heartily recommend a careful perusal of the pamphlet before us, which gives an excellent summary of the present state of knowledge in regard to a most important and very common disorder.

Literary Notes.

We have received Volume IX of the *Index Catalogue of the Library of the Surgeon-General's Office*, U. S. Army. This volume extends from Medicine (popular) to Nywelt. It contains 13,151 author-titles, representing 6,834 volumes and 12,818 pamphlets It also includes 9,999 subject-titles of separate books and pamphlets, and 29,120 titles of articles in periodicals. Like its predecessors, it reflects great credit upon the editor, Dr. Billings, and is an evidence of the wise liberality of the National Government.

CORRESPONDENCE.

Professional Cowardice.

TO THE EDITOR.

Sir: The purport of this communication is to inform Dr. W. R. D. Blackwood of your town, that he is living in advance of his age. The subject upon which he writes so bravely and sensibly in the main, is tabooed.

Some years since a short paper of mine on "The Limitation of Families" was published in a prominent medical journal, and while possessing no special merit or originality in itself, seemed to interest the medical profession immensely. I have now in my possession, a large pile of letters coming from all sections of the country, from Maine to Texas, as a result of that communication, in which I took substantially the same grounds as has Dr. Blackwood. They were mostly from physicians, of course. But quite a number came from laymen and women and they were invariably commendatory.

The prevalence of evil practices was admitted and deprecated and the universal request for information as to how this prevention could be accomplished, was noticeable.

As a matter of course I had nothing absolutely new to recommend; but having tried to inform myself concerning all the approved, safe and certain methods, I wrote a second article in which I described *the* method which in my hands has proved efficient—which I have recommended for many years and do so recommend still, and which has, if carefully followed out in detail, invariably given satisfaction—and what was the result? I have yet the letter from the editor of the aforesaid journal in which he says, at least this is the purport, if not the exact wording:

"There is no fault to be found with the plan you recommend, but we question whether the time has yet come to describe so boldly, even in a medical publication, these *very specific* instructions for limiting progeny; and while we do not absolutely refuse to publish your article, we deem it best as a matter of *policy* in deference to *public opinion* to withhold it for awhile."

It is not necessary to add that it was never published, and to this day I have been annoyed by the clamor my professional contemporaries kept up in order to find out how to prevent conception, "*tuto, cito, et jucunde.*"

That information, I am apprised, is not timely, nor decorous, nor in accordance with the spirit of the nineteenth century; therefore I withhold it.

But I denounce such false modesty, and I protest, with all my might, against a squeamishness wholly in the interest of crime.

However, I shall get rude and personal if I keep on, therefore a period is the proper punctuation right here.

Very truly yours,

DAVID E. MATTISON, M.D.

Warsaw, N. Y.

Biliousness.

TO THE EDITOR.

Sir: When I commenced practice thirty years ago I frequently heard my neighboring physicians use the terms: "*Bilious,*" *and* "*Torpidity of the Liver.*" In the study of medicine I had never seen those terms definitely explained, and I often wondered what was the true pathology of the condition meant. When I had become more acquainted with those practitioners, and my student-life timidity had worn away, I made it a point to question and cross-question those who made use of these terms in consultation or in medical discussion, as to their meaning. I never got a satisfactory reply from any of them, but received the impression that none of them had any definite idea of what was meant by the terms. I asked one physician, who was a professor of practice in a college of some note, what pathological state he intended when he said "*bilious,*" and he replied: "I do not know; it is a term in common use; but what the true pathology is I never made out. It is a convenient term to apply to cases accompanied by a sallow skin and a general malaise."

Just here is the explanation of their general use. The patients accept the pathology expressed by those terms without any question, and the physician avoids further trouble to investigate the case and writes a prescription with a view to stimulate the liver, and arouse it into action, and gives the case no further thought.

After thirty years of practice I find even well-educated practitioners still using the terms "*bilious*" and "*torpidity.*" The medical journals, too, are not exempt from them to-day, though they are loose, meaningless, and unscientific. Medical students, in their text-books on physiology and pathology, do not meet with them. But soon after getting into practice they learn

them, and find a good use for them, to shield their ignorance. They never drop them, so long as they carry calomel, blue-mass and podophyllin, with which to arouse the *lethargic condition of the liver!*

If one will refer to his physiology (modern) he will learn what the functions of the liver are (so far as are known), and see that "*torpidity*" is a myth. Why not drop the terms, as educated physicians, from the medical nomenclature, or use them among patients as we use Santa Claus with little children? deceiving them, but not deceiving ourselves?

I have found quite a large class of pathological conditions, each requiring different treatment, that may have been designated by those terms, by the careless physician who takes but little pains to investigate his cases, and trusts to luck for the good results of his liver stimulants. Such are: gall-stones, gastric and gastro-intestinal catarrh in its various forms, over brain-work, hard labor with under feeding, various kidney, heart and lung affections, peritonitis (chronic), affections of the pelvic viscera, and numerous other obscure diseases.

Yours truly,
JOHN M. CURRIER, M.D.

Newport, Vermont,
Oct. 9, 1888.

NOTES AND COMMENTS.

Small-pox among the Indians.

Official information was recently received by Dr. Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, from the Secretary of the New York State Board, of the existence of small-pox among the Indians of the Cataraugus and Allegheny Reservations in that State, he at once telegraphed instructions to Dr. J. L. Stewart, of Erie, Medical Inspector to the Board for the Lake District, to visit the Cornplanter tribe in Warren County, the members of which are in constant communication with those of the New York reservations, and take the necessary means for their protection The instructions were carried out with commendable promptness. The entire tribe was vaccinated, and the chief, Marsh Pierce, promised to forbid his people crossing the border, until the disease had disappeared. He rendered every assistance to the vaccine physician and extended the thanks of himself and his people to the State Board for its timely action in their behalf.

A Lay Opinion of Sir Morell Mackenzie's Book.

The conversion by Dr. Morell Mackenzie of his record of the sufferings of his patient, the Emperor Frederick, into merchandise of the lowest kind, and the sale of it to a disreputable sensational Sunday newspaper in this city for a good round sum, strikes us as one of the shabbiest and least professional acts ever committed by a member of a noble calling. A quarrel of doctors over a dead body is always a rather repulsive thing, doubly repulsive when the body is that of a man at whose bedside the whole civilized world watched with sorrow and respect. We can readily conceive, however, that Dr. Mackenzie may have found it necessary to lay before the public a full account of the sickening details of the progress of the dreadful and fatal disease, owing to the assaults made on his professional reputation. We are treated to so many of these clinical horrors, nowadays, whenever a distinguished man dies, that doctors are naturally more and more ready to supply them on small provocation. But surely the vindication ought to have been made in the quietest and most professional way, and addressed as far as possible, in form as well as in fact, to a professional audience only. Does any layman or laywoman whose literary tastes are not thoroughly morbid or depraved care to follow in minute detail the history of a fatal cancer in the throat? But what are we to say of a doctor who makes a sort of popular novel out of the story of his patient's horrible sufferings, and sells it then for a large sum to one of the most enterprising purveyors of nastiness in the world? The arrangement has miscarried through somebody's dishonesty; but it is very rare indeed for a thief to render indirectly such good service to the cause of decency as this one has done.—*Nation*, Oct. 18, 1888.

Artificial Carlsbad Salts.

The fulsome advertisements of these salts in various ways may have tended to obscure the fact that very cheap and effective artificial preparations can be made. One of these is that suggested by Ziemssen:

Sulphate of sodium	40 parts.
Carbonate of sodium	6 parts.
Chloride of sodium	1 part.

This should be dissolved in hot water, then the latter evaporated, the remaining salt powdered, and a proper dose of this (one-half teaspoonful) taken in hot or carbonated water.—*Medical Record*, July 21, 1888.

Medical Legislation in New York.

It is more than probable that additional legislation will be sought from the next Legislature of New York to control the practice of medicine. Mr. W. A. Purrington, counsel for the Medical Societies of New York County and State, recently read a paper before the American Social Science Association on the extent to which legislation can aid medical education. Legislators will do well to study this paper before introducing any new laws pertaining to the subject. Mr. Purrington thinks that a responsible board should be created, which will have in charge the arrangements of quarantine and sanitation, and also the licensing of medical practitioners of every sort; for he contends that the dentist and the pharmacist should be recognized as medical men. All that legislation can do to aid medical education he believes can be summed up as follows:

1. By fixing a minimum age under which they (physicians, dentists, and pharmacists) will not be allowed to practice their calling.

2. By requiring of each of them a fixed term of study of certainly not less than two graded years, leaving to the board the care of details.

3. By requiring proof by examination or certificate that each candidate for license had studied, before beginning his professional course, at least those branches in which law students are examined in this State before they commence their legal studies.

4. By declaring that no medical schools (including in the term schools of dentistry, pharmacy, and midwifery) shall be incorporated by special act, and providing a general law for the incorporation of such schools, only upon proof made of the possession by the incorporators of sufficient capital—say, not less than a hundred thousand dollars—and a teaching plant, to justify the belief that the school will be capable of exercising faithfully its franchise. Such an act should contain stringent provisions for its own enforcement and for the forfeiture of abused charters.

5. A minimum course of medical study should be prescribed, in which a grade of at least seventy per cent. should be attained on examination. The regulation of all details of the examination should be left to the board. But the topics in which the examination should be had might well be specified in the statute. It might be well to omit the topics of therapeutics and materia medica, upon which all medical heresies have been begotten by unscientific minds, inferring that one who should creditably pass his examinations in botany, chemistry, physics, anatomy, surgery, physiology, hygiene, diagnosis, obstetrics, and microscopy, especially if his clinical examination should show him to be educated in a true sense to observe and draw sound deductions from observation, might be trusted to form his own conclusions and pursue his own studies as judgment should dictate in the field of therapeutics. The law can have nothing to do with medical theories. The utmost it can do successfully is to prescribe that none shall practise medicine except persons educated in those branches of science that all admit are essential to an understanding of morbid conditions of our species, and possessed besides of a fair general education.

6. Finally, the law should not recognize any diploma as of itself conferring a right to practise medicine: even if the possession of such document should be required as an antecedent to examination by the health board, it should not be allowed to take the place of such an examination. Any scheme of medical legislation will hereafter embrace that great safeguard against imposture and efficient tracer of frauds, the system of registration, where no one is allowed to practise medicine who has not made a public record, under oath, of his name, origin, and credentials for a license.—*Science*, Oct. 19, 1888.

New Laboratory for Cornell.

The Board of Trustees of Cornell University recently appropriated $80,000 from the permanent funds of the university for the erection of a chemical laboratory. A new chemical building is made necessary by the great increase in the number of students within a few years. The sum thus taken from the permanent funds will be replaced by deducting $20,000 a year for four years after 1890 from the regular income of the university. Work on the new building will be begun at once. This will make the fourth large building in process of construction on the campus, one of them, the library, costing $225,000. The trustees appropriated $40,000 to complete the new Engineering Building, an imposing brown-stone structure, called Lincoln Hall, in honor of the President, who signed the Morrill Land-Grant bill.

Rewards for Discoveries and Inventions.

The Committee on Science and the Arts of the Franklin Institute, of Philadelphia, Pa., announces the fact that the Committee is empowered to award, or to recommend the award of, certain medals for meritorious discoveries and inventions, which tend to the progress of the arts and manufactures. These medals are:

1. *The Elliott Cresson Medal* (Gold).—This medal was founded by the legacy of Elliott Cresson, of Philadelphia, and conveyed to Trustees of the Franklin Institute. By the Act of the Institution, May 17, 1849, the Committee on Science and the Arts was designated and empowered to award this medal, and the Committee decided to grant it, after proper investigation and report by sub-committee, either for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process, or combination of materials in manufactures, or for ingenuity, skill, or perfection in workmanship.

2. *The John Scott Legacy Premium and Medal* (twenty dollars and a medal of copper).—The John Scott Legacy Premium and Medal was founded in 1816, by John Scott, a merchant of Edinburgh, Scotland, who bequeathed to the City of Philadelphia a considerable sum of money, the interest of which should be devoted to rewarding ingenious men and women who make useful inventions. The premium is not to exceed twenty dollars, and the medal is to be of copper, and inscribed "*To the most deserving.*"

The control of the Scott Legacy Premium and Medal (by Act of 1869) was transferred to the Board of Directors of City Trusts, and referred by the Board to its Committee on Minor Trusts, and that committee resolved, that it would receive favorably the name of any person whom the Franklin Institute may from time to time report to the Committee on Minor Trusts, as worthy to receive the Scott Legacy Premium and Medal. The Franklin Institute, by resolution in 1882, accepted the above-named action of the Committee on Minor Trusts, and referred the duty of making such recommendations to the Committee on Science and the Arts. The Committee determined that the recommendation for such reward shall be made on the favorable report of a sub-committee which shall be appointed to examine the invention or discovery.

Upon request, from interested parties, made to the Secretary of the Franklin Institute, full information will be sent respecting the manner of making application for the investigation of inventions and discoveries; furthermore, the Committee on Science and the Arts will receive and give respectful consideration to reports upon discoveries and inventions, which may be sent to it with the view of receiving one or the other of the awards herein named, and full directions as to the manner and form in which such communications should properly be made will be sent on application. Inquiry may be addressed to Wm. H. Wahl, Esq., Secretary.

Easy Method of Producing Large Anatomical Diagrams.

Mr. W. T. Thomas, in a letter to the *Lancet*, August 11, 1888, says that he has found thin sheets of mica coated with a varnish of one ounce of dried Canada balsam to two ounces of benzole to answer admirably. His mode of procedure is described as follows: Having coated the mica with varnish, lay it on the picture or engraving to be enlarged, trace the outlines on the varnished surface with a fine drawing pen and liquid Indian ink. Place this as the slide in an ordinary magic lantern (oil lamp gives ample luminosity—I use an Argand reading light in the lantern) and the picture is enlarged to any size according to the distance of the lantern from the screen. I find it is better to use the wall as the screen where the paper or calico is hung, and it is an easy process to run over the outline on the material with a soft crayon. The tracing, fitting up, and drawing occupy on an average a quarter of an hour. Enlarging on the blackboard so that the lecturer may fill in is easily done by this method, the room being slightly darkened, absolute darkness not being necessary as only black lines are required, and no fine features or tracery.

Chloride of Ethylene and the Cornea.

Nature, Sept. 13, reports that at the meeting of the French Academy of Sciences, Sept. 3, M. Raphael Dubois submitted a paper descriptive of experiments on the physiological action of the chloride of ethylene on the cornea or covering of the eyeball. The author showed that the chloride of ethylene introduced in any way into the system produces in the dog, several hours after waking, an opacity of the cornea of a very remarkable character. In his experiments he studied the nature of this phenomenon, and the mechanism by which it is produced.

"The Triumphs of M. Pasteur."

Under this heading the *Intransigeant*, of September 10, gives a list of six persons who have died recently of hydrophobia, after having submitted to the "infallible" inoculations of the method of Pasteur. The journal had previously, September 6, announced the death of a boy, named Villemain, of Marseilles, who died June 23, after inoculation. The six new cases are as follows:

1. Bertin (of Gentilly).—Bitten May 15 by a mad dog; inoculated on May 17, and for 24 days after. Died of hydrophobia, June 20, 36 days after the bite.

2. Labeaume (laborer, of Châtenay).—Bitten May 29 by a mad cat. Treated at the Institut Pasteur, from May 30 to the 14th and 29th of June. Died, rabid, July 6, at Versailles Hospital, 36 days after the bite.

3. Ducos (of St. Jean de Bonnefond).—Bitten June 16 by a mad cat. Inoculated from June 20 to July 7 (18 days). Died of hydrophobia at the Hôtel Dieu, at St. Etienne (Department of the Loire), 32 days after being bitten (July 18).

4. L. Mesnil (of Châtenay), aged 44.—Bitten March 25 by a mad cat. Treated at the Institut Pasteur from March 26 to April 12. Died, rabid, July 30.

5. Mdme. Sarasin (of Saint Meurice, Switzerland), aged 44 years.—Bitten July 1 by a mad dog. Treated at the Pasteur Institute Died, rabid, at the Broussais Hospital, August 4, 35 days after the bite.

6. Guers, Joseph (of Chelles).—Bitten July 13 by a mad dog. Inoculated from July 16 to August 6 (20 days). Died, rabid, at the Necker Hospital, under the charge of Professor Peter, 26 days after the bite (August 8).

Remark should be made that, with the exception of the case of Mesnil, all these inoculated persons died in less than 40 days after being bitten; that is to say, that instead of *retarding* the progress of the virus, the inoculations by Pasteur accelerated it. The average period of the incubation of the malady, without treatment, is from 40 to 50 days. And after these hecatombs have mournfully proved the impotence and the danger of his anti-rabid inoculations, M. Pasteur begins now to speak of preventive inoculations for cholera. It is a case of senile dementia which will lead up to a real social peril under the sanction of Government.

7. In addition to the above cases, the *Medical Press*, of July 7 last, reported that "a man, aged 28, who was bitten by a rabid dog in the month of December last, had just died. He was treated by Pasteur immediately after the accident."

8. The *Lancet*, September 15, has an account of the cases announced by *L'Intransigeant*, with the addition of the following: "A child, at Marseilles, aged 31 months, who was bitten on May 9 last by a rabid dog, and treated at the Pasteur Institute from May 14 to June 9, died from rabies on June 23—fourteen days after the end of the treatment." From a statement published in the *Annales de L'Institut Pasteur*, we find that these details referred to the case of Villemain, mentioned in the first few lines of this record.—*Zoöphilist*, Oct. 1, 1888.

Explosive Mixture.

The *American Journal of Pharmacy*, September, 1888, says: A serious accident happened in Topeka, Kansas, on the morning of August 14, when Dr. Detlor, a veterinary surgeon, attempted to powder in an iron mortar a quantity of saltpetre and sulphur. On striking the mixture with an iron pestle a violent explosion took place, shattering the mortar and resulting, besides serious damage to property, in the wounding of the operator, whose left hand was completely blown off, the right hand pierced and mutilated, and a leg and other parts of the body lacerated. Several other persons were more or less seriously injured and a horse on the opposite side of the street was wounded.

Crowley's Brain.

The brain of the dead chimpanzee, Crowley, has been examined by Dr. Spitzka. He finds that it weighs a third less than the average human brain, but is more like a human brain than that of any other chimpanzee whose head has been opened. Dr. Spitzka found faint white streaks at the floor of the fourth ventricle, which, when fully developed in man, are supposed to be connected with the highest functions of hearing, such as the power to distinguish the different words of a language. The auditory streaks are not found in deaf mutes, but have been found poorly developed in the brains of imbeciles and well developed in the brains of intelligent persons. Their presence, though very faintly developed in the brain of Crowley, is regarded as an interesting discovery. Dr. Spitzka, however, thinks that the power to develop in Crowley was very limited.

A Cunning Malingerer.

The Paris correspondent of the *Therapeutic Gazette*, August, 1888, says: "An amusing case of malingering was the other day related by an army doctor. A soldier was suspected of feigning a cystitis, from which he claimed to be suffering severely. He had thus secured exemption from many irksome duties; but the surgeon mistrusted the man, partly because army doctors are naturally incredulous, partly because the appetite remained excellent, and chiefly because the patient always found some pretext for passing the bloody urine when no one was present. Once, however, he was compelled to officiate while the surgeon was watching him. The blood was there, sure enough, only with the last drops passing a most unnatural hissing noise was noticed, as if some gas were escaping from the bladder. Suspecting a trick more than ever, the doctor, at the next micturition, ordered a hospital nurse to draw with a catheter the water from the bladder direct, when lo! and behold! a beautiful specimen of normal healthy urine was obtained. Caught at last, the soldier confessed he had first dropped into his urine blood squeezed from his gums, and, when something more convincing became necessary, he had blown it himself into his bladder by means of a common grass stem. Hence that wonderful escape of gas observed before the final collapse of the deception."

Dissimilarity of the Knee-Jerks in Ataxia.

At the meeting of the Congress of Polish Physicians and Naturalists at Lemberg, July 18–22, 1888, Dr. Goldflam, of Warschau, spoke of the dissimilarity of the knee-jerks in the two limbs in locomotor ataxia. After careful study he is led to the conclusion that this symptom is a very early one and of great value in diagnosis. He observed it at the time when paræsthesias or neuralgic pains first appeared, and when the knee-jerk was present on both sides, but was different. In all these cases the knee-jerk subsequently disappeared. Cases of locomotor ataxia in which the knee-jerk is retained are very rare. Goldflam refers to one case in which it was diminished; one in which it was diminished only on one side; five cases in which it was exaggerated—probably cases of combined degeneration; and seven cases in which it was retained, but was unequal on the two sides.—*Wiener med. Presse*, September 9, 1888.

American Medical Association.

The fortieth annual meeting of the American Medical Association will be held at Newport, R. I., June 25, 1889, having been postponed from the date first decided upon (June 4) in order to hold its sessions at the time of the celebration of the 250th anniversary of the settlement of Newport. The later date was also found to be more convenient for the local societies. The Committee of Arrangements consists of: Drs. H. R. Storer, Chairman; C. F. Barker, M. E. Baldwin, C. A. Brackett, J. P. Curley, P. F. Curley, J. P. Donovan, H. Ecroyd, Jr., V. M. Francis, T. A. Kenefick, G. M. Odell, F. H. Rankin, W. C. Rives, Jr., S. H. Sears, W. S. Sherman, H. E. Turner. W. Thornton Parker, Local Secretary.

The Associate Committee appointed by the Rhode Island Medical Society, consists of Drs. G. D. Hersey, W. H. Palmer, G. T. Swarts, all of Providence, R. I.

American Academy of Medicine.

The American Academy of Medicine will hold its next annual meeting at the New York Hospital, Tuesday and Wednesday, November 13 and 14, 1888. Papers will be read by Drs. H. I. Bowditch, of Boston; Theophilus Parvin, of Philadelphia; Leartus Connor, of Detroit; L. D. Bulkley, of New York; J. C. Wilson, of Philadelphia; E. Andrews, of Chicago; George J. Fisher, of Sing Sing, N. Y.; C. C. Bombaugh, of Baltimore; R. L. Sibbet, of Carlisle, Pa.; W. F. Waugh, of Philadelphia; and the President's Address, by Dr. F. H. Gerrish, of Portland, Maine.

Dr. Richard J. Dunglison, of Philadelphia, is Secretary.

Ohio State Sanitary Association.

The sixth annual meeting of the Ohio State Sanitary Association will be held at Canton, Ohio, November 14 and 15, 1888. An interesting programme has been provided. Dr. G. C. Ashman is President, and Dr. R. Harvey Reed Secretary, of the Association.

American Public Health Association.

The American Public Health Association will hold its sixteenth annual meeting in Milwaukee, Wis., Nov. 20, 21, 22, 23, 1888. An interesting programme has been published. Dr. Irving A. Watson, Concord, N. H., is Secretary.

NEWS.

—Captain John Jellard has died of yellow fever in St. John's Hospital, Brooklyn. There is no occasion to fear a spread of the disease.

—Dr. Löhlein has been offered the chair of Gynecology at the University of Giessen, which was made vacant by Prof. Hofmeier's resignation.

—H. M. Whelpley, Professor of Microscopy in the St. Louis College of Pharmacy, has written an instructive paper on microscopy of drugs mentioned in the U. S. Pharmacopœia.

—A committee appointed by the Los Angeles County Medical Society reported back to that society that there were in that city on Sept. 7, 1888, 256 practitioners, only 140 of whom were recorded in the Clerk's office; in other words, nearly one-half of them were practising in violation of the law.

HUMOR.

PHYSICIAN (to convalescent patient)—"My bill, sir, for attendance during your late illness." Patient (looking over bill and turning white)—"Great Scott! Doctor. Was I as sick as all that?"

WHERE THE POEMS WENT.—"Is the editor-in-chief in?" asked a stranger, as he sauntered into the city reporters' room at 8 o'clock in the morning. "No, sir," replied the janitor, kindly, "he does not come down so early. Is there anything I can do for you?" "Perhaps so. Are you connected with the poetical department of the paper?" "I am, sir." "Oh, what do you do?" "I empty the waste baskets, sir."—*Milwaukee Sentinel.*

AGING AS A FINE ART.—"There, you look ten years older now," said a down-town barber yesterday as he released a man from the meshes of a towel and yelled "Brush!" To the customer who followed he said: "That was a young fellow who has just started in business here as a doctor. He looked too young, and, to get patients, he had to grow old in the barber's chair. Can we age a man? Well, I should say so. It's a part of our trade. Let me take you in hand and dress your hair and beard my way for a month and you'll look a middle-aged man. It's all in the appearance. People won't trust a young doctor if he looks too young, and I am adding years to the appearance of half a dozen young physicians now."—*Chicago Herald.*

MARRIAGES.

MYERS—SNYDER.—On October 11, 1888, by Rev. F. Berkemeyer, A. F. Myers, M.D., of Blooming Glen, to Miss Wilhelmina Snyder, of Sellersville, Bucks Co., Pa.

GRIM—FETTER.—On October 18, 1888, by Rev. D. Sevin Coleman, George M. Grim, M.D., of Ottsville, to Miss Sarah E. Fetter, of Churchville, Bucks Co., Pa.

GROOM—HUTCHINSON.—On October 23, 1888, by Rev. Dr. J. M. Knox, President of Lafayette College, Albert Groom, M D., to Miss Margaret Hutchinson, both of Bristol, Bucks Co., Pa.

OBITUARY.

LEWIN H. COHEN, M.D.

Dr. Lewin H. Cohen was born in Scotland in 1842, and died at Aiken, S. C., September 27, 1888. After an excellent preliminary education, Dr. Cohen was graduated from the New Orleans School of Medicine, February 15, 1862. He served for a time in the military hospitals of the Confederacy, and later engaged in practice in the city of New Orleans, and held the chair of Adjunct Professor of Chemistry in his *Alma Mater*. In 1868 he returned to Quincy, where his family resided. During the last twenty years he has been engaged in practice in Quincy, except for a period of a few months during which he occupied the chair of chemistry in the Louisville Medical College.

At the time of his death, and for several years before it, he was Professor of Chemistry in the Quincy College of Medicine. At different times he was connected with the Board of Health of Quincy, where he became noted for his efficient service. He devoted much time and study to sanitary science, and was a member of the American Public Health Association, and other sanitary societies.

He served as Secretary of the Adams County Medical Society for several years with great acceptance, and contributed liberally to its discussions.

In his intercourse with his medical brethren he was scrupulously observant of the amenities and ethics of the profession. Of scholarly tastes, he had an appreciative knowledge of general literature, as he had also of the higher forms of art, and maintained under all circumstances the character of a cultivated gentleman.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

CLINICAL LECTURE.

THE TREATMENT OF INTESTINAL INDIGESTION.[1]

BY SOLOMON SOLIS-COHEN, M.D.,
PROFESSOR OF CLINICAL MEDICINE AND APPLIED THERAPEUTICS.

Gentlemen: Among the cases we have had before us this week, a number in which the same diagnosis was made, are deserving of some detailed attention, not because of their rarity, but of their great frequency. Although the diagnosis was the same, the treatment of different patients varied in several particulars. The lack of success that often attends the management of these cases may, I think, be attributed to the routine treatment into which one is only too liable to fall, and which, because of its apparent benefit in very many instances, is applied to all without discrimination. But there is another reason for failure; especially in patients who, like the young woman we have had here to-day, wander from physician to physician, and from dispensary to dispensary, varying the circle with devotion to different infallible remedies placed upon the market by disinterested benefactors of a suffering public. The element of failure which I refer to is disregard of your directions by the patient. When such a case comes into your hands in private practice, refuse to take charge of it unless your advice is obeyed religiously; otherwise you will simply be added to the number of doctors "who did no good."

A few words as to the facts upon which we based our diagnosis, in order that from these we may derive hints as to our therapy. Our patients have all complained of pain, of pain associated with the taking of food, though the association has varied and in one case was only developed by persistent questioning. In general, the location of the pain was below the diaphragm, but in the instance of the young woman already referred to, not only was the association of the pain with food-taking hard to develop, but its location was in the præcordium—in fact the patient came to us with a home-made diagnosis of heart-disease, in which doubtless she had been encouraged by some of the quacks and patent-medicine venders she had visited. Now this location of pain in the cardiac area, associated as it often is with breathlessness, with palpitation of the heart, and with not infrequent sensations of faintness, may mislead not alone the patient but also a careless medical adviser. Make it a rule never to accuse the heart until you have excused the stomach. This patient has not even a condition that may with justice be termed functional disturbance of the heart, for the fluttering is purely a secondary matter, and will disappear with the cause of it; namely, irritation of the pneumogastric nerve-endings by decomposition products in the stomach and duodenum; and we need not think of cardiants among the remedial agents to be applied. I have called her case, like our others, intestinal indigestion, because the principal failure of function seems to be in the upper bowel; but the existence of this præcordial pain, and the facts that it is relieved by taking food (the obscure association which we had to seek for); that it comes on at a time when the stomach is empty, or ought to be, some

[1] Delivered at the Philadelphia Polyclinic and College for Graduates in Medicine.

three hours after a light breakfast; and that it is sometimes relieved by the expulsion of a sour liquid, water-brash—show that the gastric mucous membrane is also at fault. The pain is not a cardiac pain in any degree; it is gastric: and it results either from the prolonged pouring out of hyperacid gastric secretions, or more probably from the presence of some of the fermentation acids resulting from the decomposition of retained food, acting upon the unprotected mucous membrane of the stomach. Hence the relief on the taking of food, whether from mere mechanical absorption of the acid fluid, or of from chemical and digestive reactions. Hence also the relief which in many of these cases results from the administration of alkaline waters, or even of simple hot water, which dilutes the stomach-contents and flushes out the viscus. If we have reason to consider this acidity due to actual abnormal secretion of an altered gastric juice, we can appropriately resort to the expedient of repressing that secretion by a minute dose of one of the mineral acids, upon the well-known principle, that acid applied to the orifices of acid-secreting glands, checks their activity; but if we have reason to believe as in the case before us, that we are dealing with acid products of fermentation, we must depend upon alkalies for palliation, and upon the prevention of fermentation for cure. But we have been told also, by other patients, of pains below the diaphragm; sometimes referred to the region of the stomach; sometimes to various portions of the abdomen, sometimes diffuse, as indicated by the whole hand being used to indicate the locality, or by to and fro motion of the hand, laterally or longitudinally; sometimes localized, as when one or two fingers are used to point its site. Now ordinarily, if but one or two fingers, especially finger-tips, are used to indicate the site of pain, we are justified in suspecting a purely local cause, and in the presence of other gastric or intestinal symptoms we must not forget the possibility of ulceration. Indeed in every case of pain we should always interrogate the locality; though very often the lesion is more or less distant from the seat of pain, even where local inflammatory or ulcerative processes in internal viscera are its cause. Many cases are even on record of pain persistently ascribed by the patient to one organ, due to morbid conditions in another, not thought of. Nor can we be sure in the case of disease of the thoracic or abdominal viscera, that the site of pain indicated by the patient, externally, has any immediate topical relation with the seat of lesion. However, in these cases of ours now under consideration, neither local examination nor any of the symptoms has given us reason to suspect any structural lesion. The seat of pain in the greatest number of instances has been the right hypochondrium or hypogastrium, and its extent has been indicated by three or four fingers. It is rarely constant, and usually begins an hour or two after eating, or reaches its height of exacerbation at that time. Its duration varies from twenty minutes or so, to hours. An associated pain in the left hypochondrium will be found to have less obvious connection with the taking of food, and to be due in most instances to a distended colon, disappearing with the relief of that condition. The flatulence and abdominal distension, present in greater or less degree in all our cases, point to the formation of gases of decomposition in the intestine; while the belching and sour eructations in one of them point to the same condition in the stomach as well. We have irregularity in the alvine movements, constipation alternating with diarrhœa, but the former condition predominating. The discharges contain considerable mucus, and are in the majority of instances light, or even clay-colored from deficiency of bile. There is more or less irregularity in the hepatic function; and although enlargement of the liver could be detected in but one of our cases, in several instances there has been slight tenderness upon pressure over the site of the liver. A jaundiced complexion has been noted in but one of our patients, though slight discoloration of the conjunctiva has been found in several. In accordance with my invariable routine I have examined the urine in all of these cases, but have not found anything significant. We have been able to elicit in several cases, and we are justified in assuming it to be true in the others, that nitrogenous foods, meats particularly, cause much less discomfort than starchy and fatty aliment. In the case of the seamstress living on bread and tea, the pallor and general weakness indicated that we will have to deal with an altered condition of the blood, a veritable anæmia, as well as with the local intestinal trouble; but before we can expect any good results from our corroborant treatment in this case, we must put the digestive canal into condition to perform its functions.

Observe the expression, gentlemen, the digestive canal. We are too much inclined in cases of disordered digestion, whether

chronic or acute, whether due to local disease or occurring in the course of fever or other systemic disturbance, to concentrate our attention upon the stomach. But the stomach is by no means the sole organ of digestion; or even the principal one. I am not at all satisfied that we thoroughly understand the physiology of digestion as yet, nor that it is the comparatively simple process described in some text-books. Still we do know the general outlines of the process with sufficient exactitude to base upon that knowledge a rational therapeusis.

Assuming as correct the division of foods into nitrogenous (proteids), and non-nitrogenous, the latter consisting of the two groups, carbo-hydrates or starches and sugars, and hydro-carbons, or fats and oils; we know that while the gastric juice exerts its action almost, if not quite, exclusively upon nitrogenous foods, the salivary pancreatic and intestinal secretions are capable of acting upon all foods. Thus, if gastric digestion were even to come to a stand-still, nutrition could still be maintained; while the total abolition of all but gastric digestion would result sooner or later in wasting, from deprivation of the non-nitrogenous elements of the food.

It was suggested by so great an authority as Claude Bernard that the function of the gastric juice was to prepare the nitrogenous aliments for further and complete digestion by the pancreatic juice, and so careful and experienced an observer as Sir Wm. Roberts is strongly inclined to the same view. Be this as it may, we must not overlook the existence of the pancreas and neglect its functions in the consideration of the conditions actually calling for remedy in our cases of so-called dyspepsia. In fact, I am more and more led to the view that we should assume all cases of dyspepsia to be intestinal indigestion, unless we have clear evidence to the contrary; and I am certainly getting much better results in treatment, than when I thought of the stomach first. However, in the cases we have had here, all the evidence has gone to show that the intestine is at fault, and we can therefore base our treatment upon that fact. We have to correct some condition of the mucous membrane of the duodenum and the upper intestine which prevents the proper action of the digestive fluids in that portion of the alimentary canal; and we have also very probably to deal with a resultant condition of impaired function of the pancreas, and in a less degree of the liver.

The first indication is to cleanse the mucous membrane from the mucus and other catarrhal products which, mingling with the undigested food, invite the fermentative change in the presence of the organisms always abundant in every place communicating with the atmosphere. We can do this to a great extent by copious draughts of water, preferably hot water, as more likely to produce a good local effect upon the chronically inflamed mucous membrane, by its action upon the vessels. This should be administered from half an hour to an hour before meals. Should it prove inefficient we shall resort to lavage, or washing of the stomach, which however is for obvious reasons less efficient here than in cases of presumably uncomplicated gastric catarrh. Secondly, we must for a little while restrict the amount of food passing for digestion into the intestine, and in particular those kinds of food, namely the starches, sugars, and fats, which so largely depend upon the intestinal processes for their disposition. In this way we cut off the supply of fermentative material. Thirdly, we must gently stimulate the pancreas to the production of an increased and altered secretion. Fourthly, we must try to substitute artificially the deficient pancreatic juice until it shall be poured out in sufficient quantity. And finally, and to the patient's mind of more immediate importance, we must try by palliative measures to relieve the pain and other distressing symptoms, while we are endeavoring to remove permanently their cause. The diet then must be largely nitrogenous—underdone meat, milk, fish, eggs, poultry, soups and broths. If necessary, aliment may be partially predigested, but this expedient has not been indicated in the cases under review. Bread is cut down to the smallest quantity consistent with comfort; potatoes and similar vegetables are interdicted entirely, while the leguminous and succulent vegetables are permitted, in order to secure a sufficiently varied diet. Rice, too, of the starchy foods may be allowed, if it is well cooked so as to soften the grains thoroughly. Sweets, pastries, fats, with the exception of moderate amounts of butter, are prohibited, and as a matter of course, frying is forbidden as a method of cooking. It is a mistake, however, to restrict the diet too much, or to maintain even the moderate restrictions suggested, for too long a time. We must endeavor to put our patient as soon as possible into such condition that he may eat any legitimate food placed before him. The administration of Hoffmann's anodyne

immediately before meals, I have found to be very often efficient in the relief of pain, while it acts as a partial solvent for the small amount of fats permitted, and plays the part of the gentle stimulant of pancreatic secretion desired. One teaspoonful in water is the average dose. Twice that quantity may be given if necessary. Despite the theoretical objection that it cannot escape destruction in the stomach, clinical results have satisfied me that the suggestion of Sir Wm. Roberts to give an artificial preparation of the pancreas guarded by an alkali, an hour or two after the taking of food, does mechanically assist intestinal digestion. And this fulfills our fourth indication. The liquor pancreaticus prepared for Roberts is probably the best preparation, but it is difficult to obtain it at all times and places, and I have been well satisfied with the tablets prepared by Messrs. Fairchild in this country. One, two, or three of these tablets may be given, about an hour after meals, or later if circumstances demand it.

This is the general plan of treatment we have adopted in the cases we have seen together. We have, however, varied it somewhat in individual instances. In the case where præcordial pain, coming on at about eleven o'clock daily, led to a suspicion of "heart-disease," and in which we concluded that acid fermentation took place in the stomach, we gave before meals a sedative and anti-fermentative mixture of creasote, one minim, bismuth salicylate and bismuth subnitrate each seven-and-a-half grains, suspended in glycerine and peppermint water. The peppermint water was selected as having an antiseptic action, as well as furnishing an agreeable flavor. This is a slight modification of a prescription suggested by Bartholow. In the anæmic case, we gave Fowler's solution, and we added nux-vomica to the prescription in a case of excessive tympany dependent upon intestinal atony. In the case associated with jaundice we gave sodium phosphate as a cholagogue and laxative, and in several cases we gave either the official compound rhubarb pill, or our Polyclinic pill of ignatia, belladonna and podophyllin, to correct the discharges, at such intervals as were indicated by the individual conditions. We have advised our patients to take gentle open-air exercise about three hours or four hours after the principal meal of the day, but we cannot expect this advice to be carried out. Nor are we likely with these dispensary patients to secure obedience to our dietetic regulations. From these last alone in milder cases, with perhaps the compound spirits of ether for the pain, you will often be able to secure astonishingly quick relief in private practice. I am reminded at present of the case of a man who came into my office this morning to report that he had remained free from pain all summer. This patient according to his own statement had for two years vainly sought relief from a pain in the right hypochondrium, which he had been informed was due to a chronic inflammation of the intestines. I diagnosticated simply intestinal indigestion, and secured almost instant cessation of pain by the use of hot water potations and Hoffmann's anodyne in conjunction with a strict diet of skimmed milk, persisted in for two weeks; after which gradual restoration to full diet was permitted and medication intermitted at intervals, to be completely abandoned at the end of a month.

In acute returns of the chronic complaint which has yielded to treatment, a brisk saline cathartic should be administered at the outset, and the diet restricted to skimmed milk for two or three days; at the end of which time the patient will probably profess himself well. One word more as to the general management of your cases. Insist that the habit of drinking iced water at meals shall be abandoned. If any fluid must be taken with meals—and it is well to begin dinners with soup for the purpose of furnishing suitable liquid among other reasons—let it be warm. And if hot water be disagreeable, and soup be not taken or be insufficient, suggest hot lemonade. In conclusion, you will note that nothing has been said concerning pepsin, or hydrochloric acid—because in these cases they are useless.

—The City Council of Jacksonville, Fla., has passed an ordinance imposing a fine of $500 or less, or imprisonment not exceeding 30 days, upon any person who enters the city without a permit from Dr. J. Y. Porter, unless such person can prove that he has actually resided within the city limits continually since the first day of last September.

—For the week ending October 27, 1888, there were 388 cases of contagious diseases in New York City, and 54 deaths. This large number was made up as follows: Typhoid fever, 43 cases and 11 deaths; scarlet fever, 122 cases and 16 deaths; diphtheria, 105 cases and 23 deaths; measles, 117 cases and 3 deaths; cerebro-spinal meningitis, one case and one death.

COMMUNICATIONS.

MANAGEMENT OF THE NEW-BORN CHILD.

BY E. K. WELLER, M.D.,
POTTSTOWN, PENNA.

I have been incited by Dr. Ady's[1] article and the criticism of it by Dr. Bates,[2] to offer a few suggestions which may be interesting to them and should receive the attention of all obstetricians.

Improvement over ancient and traditional customs has been made in nearly everything else except in the custom of dressing babies. Let us stop for a moment to examine the customary toilet of the baby. I dress the cord in this manner: I tie it about three inches from the umbilicus and cut it another inch beyond the ligature. I then wrap it in a soft linen (preferably old linen) rag, or, better still, absorbent cotton powdered with oxide of zinc. Over this is placed a diamond-shaped pad, to the acute angles of which are attached two cords or ribbons, one at each, which are tied at the back or carried around to the front or side. We are usually taught to put on a bandage covering the whole abdomen to prevent the child from being "big-bellied" or ruptured.

Nature has made the abdominal wall elastic for a purpose—that it may accommodate itself to the varying conditions of the child's digestion. A baby is usually subject to flatulence, and if not bandaged rarely suffers any inconvenience from it because the elasticity of the walls allows the flatus to move freely through the intestines. If an adult is troubled with flatulence after meals, what a great relief it is to have a few vest buttons opened. How then is a baby expected to be comfortable with a nicely fitting band about its abdomen, thus interfering with nature's intentions and provisions? A little reflection will also serve to show that the band favors rather than guards against rupture. Suppose that a band is applied snugly and remains in proper place—which it never does, owing to the constant wriggling motion so common to the young of all animals—then the abdominal walls are prevented from expanding, and any straining as from crying, or the force of any concussion as from sneezing or coughing, being evenly distributed over the abdominal wall, will be resisted by the band, and its effects concentrated upon the weaker parts, viz., the inguinal and the femoral regions. The band protects the stronger portions and not only leaves the weaker unprotected, but endangers them by throwing upon them the whole force of any concussion.

Then comes a diaper so large that it has to be folded two or three times before it can be pinned, straddling the baby's limbs and leaving a mass of heavy and useless weight over its groins, interfering with the free use of its limbs. Next comes a little shirt made of linen or muslin, and often starched stiff with saw-teeth or some form of crochet work around the neck and arms. Surely this can have no argument in favor of its being retained as a part of a child's dress. It is cold, irritating and uncomfortable. Another uncomfortable garment, fortunately not so universally used, is the pinning blanket. Then comes the skirt with a band which is pinned around the chest under the arms, thus confining the chest and interfering with its free and proper expansion, both from its situation and its weight, it being the heavier piece of the garment. Over this is put the dress, usually made of some light material, leaving the neck, shoulders and arms with but a single, thin and cold covering. Sometimes these parts are protected by a shoulder shawl, but this is always everywhere but in the right place. Here we have a mass of humanity in its most active state pinned with fifteen pins into a bundle of heavy and unphysiological dress; and then we expect it to be healthy, comfortable and sweet-tempered! It is absurd to expect a child to rest sweetly in such a garment, and it often requires the utmost skill of the physician and teas and anodynes to quiet such a child, whereas a loosening of the band, or a pin taken out of the skin, would make it quiet.

In the dress I invariably recommend, I discard the band altogether, using instead a pad until the navel is healed. I never allow a linen shirt to be worn. The diaper should be 18 x 18 inches, made of canton flannel folded in the usual manner, and a piece 10 x 10 laid over it unfolded. This latter piece receives all the discharges and saves a great deal of work. The first garment is made up of an underskirt and night-gown, which should reach about ten inches below the feet (twenty-five inches long), and be of some soft, fleecy goods like canton flannel, which also has the advantage of not shrinking when it is washed. It should be cut princess, with sleeves to the wrists, all seams smooth, the edges around the neck and

[1] REPORTER, July 28, p. 109.

[2] REPORTER, Sept. 1, p. 285.

wrists hemmed on the outside, and at the bottom it may be fixed according to fancy; a tie and one button behind. This makes a complete fleece-lined garment, comfortable, unirritating and healthy, giving entire freedom to all abdominal and thoracic movements as well as to that continual wriggling and working of the limbs by which infants exercise and assist their development.

The next garment is made of woolen baby flannel, cut according to the same pattern, but one-half inch larger and a few inches longer—to cover the first garment—with generous arm-holes, pinked or scalloped, but not bound, with one or two buttons behind at the neck, and embroidered or plain at pleasure.

The dress is preferably cut princess to match the other garments, although any dress can be used; but I would advise them to be made much shorter than is customary, thirty or thirty-six inches being sufficient.

These three garments can be put together —sleeve within sleeve—and put over the baby's head as one garment; they button behind and the child is dressed, there being no pins except the diaper-pin.

This makes at once the easiest, simplest and healthiest way to dress an infant. It is surprising how infinitely more quiet and sweet-tempered babies are when thus warmly, loosely and comfortably clad, and how much strength and annoyance are saved the mother and nurse.

THE PREVENTION OF CONCEPTION.

BY L. HUBER, M.D., .
ROCKY FORD, COLORADO.

After the Editorial that appeared under this caption in the issue of the REPORTER for September 15, and the more recent appearance of Dr. Blackwood's sensible and excellent article on the same subject, it must needs be that some interest is felt in a further discussion of the question. As to its moral aspect I fully coincide with the views of the articles specified.

The matter is just this. There is a continuous demand made upon the physician to prevent conception and to interfere with pregnancy. This is an experience common to the practitioner everywhere, no matter what ranks or classes of society he serves. This being a fact, and furthermore there being a prevailing practice among the laity to prevent conception, sometimes with good reason, but more often, it must be regretfully acknowledged, criminally, let us ask what the profession has done by open and concerted effort to establish the legitimate grounds on which such interference could be justifiably ventured; and how many of its members have to-day clearly defined ideas on the subject? The profession has not done anything bodily to establish and propagate well-defined and intelligent notions in the case, and the physician is often left to bear weighty responsibilities alone and unsupported, or positively to refuse interference, when a broader conception of the subject would clearly define his duty to be directly the opposite course.

With this introduction I am ready to show how one great source of evil has poured out its bane for years upon the people. I refer to the fact of a low class of literature that presumes to instruct the laity in right ideas on sexual hygiene, health and comfort. Every physician knows that such books exist by the hundred and are eagerly sought, read and believed. The authors of these works are often misanthropic, shallow and unscientific writers. There are exceptions, it is true, but they are not many; so that all in all the character of the literature along this line is not much changed. Now, why should there not be a preponderance of good and reliable books instead of the grade that exists on so general and so important a subject? Why have not the best men of the profession given their labors and thought to proper sexual hygiene and thus elevated man above the mere exactions of animal desire? It seems to me that a legitimate way of preventing conception to some extent is for the profession to dispense right ideas in regard to the sexual relation and the sexual health of mankind. A large class in the community is willing to subordinate its animal instincts and desires to the restraints of intelligence and reason, and there are many persons to whom correct information on the subject would be of the greatest advantage.

We study the anatomy and physiology of the digestive organs and deem it not improper to institute experiments to make us familiar with their functions and capacity. We know that some regulation of their use is essential to their health and the health of the body in general. In the same way, I think, the sexual organs and functions should be studied. As it has been, the physician has been brought in contact almost solely with their pathology, and not with their

physiology. How many writers upon these subjects have presumed to tell us whether it is excessive expenditure of the seminal fluid or the excessive indulgence in the sexual orgasm which deteriorates and deranges the functions of the organism? Is not this an important distinction? The seminal fluid may be a very cheap secretion, on the one hand, while the nervous excitation incident to copulation may be a source of immense disturbance and wear.

The writer recollects what a professor had to say on this subject, in one of his lectures to the students of a large medical college. After diligent study of what literature there was on the subject and careful observation, the professor had concluded that the second element, as above distinguished, led to most of the evils of excessive sexual indulgence. I think it is no misrepresentation of Prof. Parvin, of Philadelphia, the lecturer referred to, to allege that this was the view he took at the time, and that it was his opinion that, for an average healthy man or woman, intercourse more than once in ten days was incompatible with the best exercise of the bodily and mental functions. This then should be the basis of a correct sexual hygiene. This fact being known to the profession, and taught by them to the multitudes with whom its members daily come in contact, would do great good, and tend to correct the evils, not only of excessive sexual indulgence, but also of frequent conceptions and pregnancies.

The profession has been negligent also in teaching the laity what is the proper time after a woman's puerperium to engage again in the rights of the marriage bed.

So much for what could be done by right knowledge and ideas along a few particular lines. We must take the case as it is, however. The demand upon the practitioner to prevent conception is an unquestionable fact. Under these circumstances, it is the duty of the profession to define more clearly what conditions justify and what do not justify interference, and then to settle upon some safe, efficient measures to meet the demand. As this work is pushed forward, criminal interference, so general and flagrant nowadays, should decline or cease altogether. The aim should be the preservation of the health and life of the race, on grounds of justification so plain and reasonable that the blood of unborn, or of untimely born, millions should not cry out against the slaughter that goes on in the very centres of civilization. There is need that this important subject should not be shunned, as it has been, by medical men, but that it should be taken up bravely and prudently, and settled in some way. If medical men leave it entirely to those who discuss it from unworthy motives, they cannot be held wholly guiltless of the consequences.

RESPIRATION EXERCISES FOR WEAK HEART AND FOR ITS DEVELOPMENT.

BY A. H. P. LEUF, M.D.,

DIRECTOR OF PHYSICAL EDUCATION AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

In my paper in the REPORTER, July 21, 1888, I considered the development of the capacity and of the muscles of the chest as being factors in shortness of breath. In the present note it is my object to call attention to the most common cause of "short-windedness," a weak heart. Puffing, blowing, and otherwise apparently inadequate breathing, are almost universally believed by the laity to be due to defective chest work; but this is a great error. We all know that the main object of respiration is the interchange of oxygen and carbonic oxide; and we also know that the signs of the inadequate interchange of these gases are those of suffocation. We know further, that these signs may be due to defective air supply to the lungs, or to defective blood supply to the lungs. The former condition was sufficiently considered in my last paper, but the latter involves heart weakness.

Careful observance of long distance runners will show that the respirations are not much increased in number during exercise, but that they are somewhat deeper than usual. On the other hand, neither are the pulse-beats much increased in number during long and continuous hard work; but they are increased in strength and volume. George Littlewood, the great six day "go-as-you-please" runner, has hardly any increase in the number of his pulse beats so long as he is in good condition. I have often examined him while he was in training for a one week's race; after having ran thirty miles in three hours his pulse beat 75 times a minute, while at the start it was beating at the rate of 70 times a minute. Long distance runners have very wide lower chests, the cartilages flaring out so that the transverse diameter of the chest is largest at its inferior edge. This expansion I do not believe to be altogether due to increased

respiratory effort, but it is undoubtedly largely due to the muscular action in running. It is a fact, though perhaps not generally known, that good running and walking involve the constant exercise of the abdominal muscles, and hence the soreness in the lumbar and iliac regions after a long brisk walk or run.

A weak heart causes shortness of breath by failing to pump through the lungs enough blood to become supplied with the oxygen required by a hard-worked organism, although the oxygen may be furnished in abundance to the lungs by respiration.

I have now briefly, and in outline, explained how "short-windedness" may be due to a weak heart, and have shown that, in long continuous work, depth of respiration and strength of heart best meet the increased demand for oxygen. Now let us inquire as to the means of detecting a weak heart.

As a rule the chest is wide and its capacity good; the pulse is weak and rather fast, being rapidly increased on relatively slight exertion; violent exertion, as for instance a hundred yards dash at full speed, causes facial lividity of a most marked type; the face has a light ashen color, the lips a light slate blue, and sometimes even the ears have a similar appearance. There are at present two men at the University of Pennsylvania who have just such an appearance after a race or training exercise; one runs a hundred yards and the other four hundred and forty yards (a quarter mile). I desire to say emphatically that all persons who show defective heart power in the way I have indicated, and as these two young men evidently have, are at any time liable to develop some form of cardiac disease. It is well known that professional athletes do not live long. They usually die of phthisis or heart disease. Why this is so, I shall try to explain in my next paper on this subject.

What is a good test of heart weakness? Any of the following answers admirably—climbing a rope, stairs, ladder, or hill; hauling and running and rowing, the latter being perhaps the severest test of all.

Persons exercising violently with weak hearts are liable to disease of the valves, to aneurism of the heart and arch of the aorta, and of the muscle substance itself. I believe that most cardiac disease arising from athletic exercises consists primarily of myocarditis, which eventually leads to secondary disease, the character of which depends upon the developmental defects of the organ, and the after life of its owner.

How to overcome heart weakness is an interesting question. Medicines may do it to a certain extent, but the strength gained is not the most serviceable that could be attained. Witness the effect of digitalis. It slows the heart's action and increases the force of its beat; but if the patient is in bed, let him sit while you notice the quickness of his pulse; or if he is up and about, let him run, and mark how quickly he becomes winded. So long as he is not really in need of a strong heart his pulse beat is good and apparently satisfactory; but when the hoped-for result is to be attained, it fails. This is not so in the case of a heart strengthened by exercise.

A teacher of mine had a hobby about the importance of daily alvine evacuations, and he would say that the rectum is a muscle to a large extent and can be trained to more effective work just like other muscles. The same is true of the heart. A great hollow muscular force-pump — why should it not be strengthened by exercise? How best to do this is the query. In answer to this question I would lay down the following generalization. Let the patient practice at those exercises which most easily cause dyspnœa. If he is "winded" running up a flight of stairs, keep him at it until he can do it without being so affected; but begin by less than the whole flight. Let him go as far as he can with comparative comfort, then rest him and let him try again and again. If this is done daily, at last the desired end will be accomplished. When this is done it will be found that his other difficulties may also be overcome without either "heartburn," palpitations, or rapid breathing. Be sure, however, always to examine the heart before recommending such a course, as you may kill your patient while trying to benefit him if he happens to have a diseased heart. The best way of all to train a weak heart is to have its owner engage in some out-door sports, as for instance rowing, running, walking, and sharp practice at base-ball, foot-ball, lawn-tennis, cricket, and hand-ball. Under such circumstances there is much mental exhilaration, nervous stimulation, and increased bodily tonicity *without any reaction.*

The mistake is usually made of overexerting the heart by too severe and prolonged exercise. The proper way to do it is in easy stages. The work should be steady, graded day after day, and never continued until there is a feeling of tiredness. It should always be stopped while an inclination is still felt to do additional work.

SOCIETY REPORTS.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of October 22, 1888.

DR. L. BOLTON BANGS in the Chair.

Dr. Alexander S. Hunter was elected President for the ensuing year; Dr. L. B. Bangs, Vice-President; Dr. John S. Warren, Treasurer; and Dr. Charles Avery, Secretary. The *Comitia Minora* was given power to publish annually a medical directory of the city of New York.

DR. PAUL F. MUNDÉ read a paper on the value of the

Operation of Shortening the Round Ligaments of the Uterus,

based on the results of 23 cases. The views which he expressed about 1884, in the *New England Medical Monthly*, and in the *New Yorker med. Presse*, are somewhat different from those which he holds to-day, principally regarding the difficulty of finding the round ligaments. In the present paper he discussed three questions which have not yet been settled regarding Alexander's operation: First, can the round ligaments always be easily found, drawn out, and the uterus thus lifted and everted? Second, in what class of cases is the operation justifiable and likely to be followed by complete relief? Third, are elevation and suspension of the uterus by shortening the round ligaments alone permanent, or is an additional operation on the vaginal and pelvic floor necessary to secure permanent relief?

Objections to the operation, he said, have been principally theoretical, or come from those whose experience has not enabled them readily to find the round ligaments. The difficulty which Dr. Mundé had formerly experienced in finding the ligaments he attributes to having followed too closely the directions of the inventor of the method. He now proceeds as follows: Standing at the side of the patient opposite the point at which the ligament lies, he feels for the pubic spine with the index finger of the left hand, and distinctly marks its situation. Then, being careful not to draw the skin to one side, he makes an oblique incision quite down to the periosteum on the spine. In the incision thus made there pouts up a little mass of tissue which should not be lost sight of during the further steps of the operation, since it contains the terminal filaments of the ligament; when this is picked up by the forceps it makes traction upon the ligament at its attachment to the pillars of the ring. Before making very strong traction upon the ligament during the replacement of the uterus, it is well, he says, to divide the nerve. The ligament varies in size from that of a knitting-needle to that of a quill, and there may be that much difference between the ligaments on the two sides. Adhesions, or too small size, of the ligaments known to exist beforehand constitute contra-indications to an operation. He said he had broken the cord three times in making traction. The entire time occupied in the operation need not be more than half an hour. Formerly he thought it was more difficult to find the ligaments in fat subjects, but he no longer holds this opinion.

In suitable cases, those in which there is prolapsus of the uterus to a certain degree, retroversion or retroflexion, non-adhesion, and relaxation of the vagina and perineum, Alexander's operation does more toward retaining the uterus in the replaced position than any other operation. There are, however, other exceptional indications for the operation. It should never be done when there are uterine adhesions, and he says it is expecting too much of it, without the aid of a plastic operation, to hold up the prolapsed uterus and vagina. Of his twenty-three cases, nineteen have proved successful, and the patients have been under observation from three months to three and a half years; the uterus has retained the position it was put in when the operation was performed. In only seven of the twenty-three cases was Alexander's operation alone performed; in others it was supplemented by plastic operations on the vagina and perineum. Dr. Mundé expressed himself as decidedly in favor of Alexander's operation in properly selected cases, and said the risk was very slight, and it caused very little pain or discomfort to the patient. None of his patients have been subjected to the test of pregnancy subsequent to the operation, as has happened to some under the care of Alexander and Dr. Polk. He does not think he would give up the operation for the one preferred generally by German surgeons—laparotomy and fixing the uterus to the abdominal walls.

DR. HANKS thought the operation suitable for some cases, but that it had been done too often in this country, had resulted in at least five deaths, and had been performed by those who would have had less difficulty in finding the ligaments had they practised more on the cadaver.

Dr. Boldt said he would limit the operation to cases of retroversion or retroflexion in which the uterus had lost all power of regaining vitality at the point of flexion; while in other cases he would employ the new method of pelvic gymnastics, which had proved so successful in the hands of some German surgeons.

Dr. Currier thought that with most men, since they lacked the expertness in finding the ligaments which came from experience, it would be better to perform Alexander's operation at one sitting, and plastic operations on the vagina and perineum at another, if they were indicated, rather than attempt to do both at the same time.

Dr. Mundé, in reply to Dr. Abbott, said he was unable to tell by the constitution or flesh of the patient whether to expect large or small ligaments.

Reports of Clinics.

COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.[1]

MEDICAL CLINIC—PROF. DELAFIELD.

Cirrhosis of Liver.

Case I.—The patient was a man, 51 years old, a porter. He dates his illness from an attack of rheumatism in the knees, about three and a half years ago. He has always been a drinking man, and for some time has been troubled with vomiting. This symptom has been aggravated during the past three years. He has been unable to eat meat and other articles of diet without distress and vomiting, and has been living upon crackers and milk for some time. He has had no appetite, has lost fifty pounds in weight, and has grown weak and unable to work. He has been of quite yellow color, but this has nearly faded away at present. His bowels have been regular; he has had no dropsy, no headache, no vertigo, no cough, and has not vomited blood. Examination of his urine showed a sp. gr. of 1021, and no albumin.

On removing the patient's clothes, his body and face are seen to be emaciated. When he lies upon his back, a distinct fulness is noted in the upper part of his abdomen. Such fulness is natural enough lower down, but observed in the epigastrium should direct attention to the organs in that region. It happens, in this case, that there is marked muscular development, which in part accounts for the fulness, but there is also undoubted enlargement of the liver. It can be felt during respiration, and is readily mapped out by percussion. Its position is normal at its upper border and extends two and a half to three inches below the free border of the ribs at its inferior edge. The liver is not increased in size laterally. It does not completely fill the area marked by dulness. It would be called a large, but not a very large liver. It feels smooth and there are apparently no adhesions. The spleen is not enlarged; the lungs are normal. The pulse is full and strong, and the radial artery can be felt to be slightly tortuous.

Here then is a man who has had a serious illness for a long time, who is emaciated and unable to work, and the only physical sign is enlargement of the liver. What is the matter with the man? He has cirrhosis of the liver, of the form that is sometimes called hypertrophic. Microscopically, the appearance presented is identical with that of the form which produces a decrease in the size of the liver.

This patient presents a good example of those cases in which the disease occurs without dropsy. Cirrhosis of the liver is liable to be associated with some form or other of dropsy, but the latter symptom is not always present. This man is quite far advanced in his disease, his health is much impaired, and yet there has been no dropsy. His loss of health is due to the fact that the inflammatory changes in the liver are such as to interfere with its functions, and malnutrition is the result.

The disease in this patient, as is often the case in cirrhosis, is complicated. The patient is suffering with chronic alcoholism and alcoholic gastritis. He has been coming to the Clinic for the past six weeks. The treatment has consisted of a regulated diet, total abstinence from alcohol, and the administration of acids and bitter tonics. He notes some improvement, but it is slight.

In these cases diet is of the most importance. There is no general rule to be laid down. Each patient has his own peculiarities. Some do best on milk alone, others on milk and the starches, others on vegetables, and others again on meat. These foods alone or combined should be given the patient, and three hours after digestion the stomach emptied by the stomach pump. It should be carefully observed just what foods are digested and what are not digested. The determination of this is not very troublesome, and it affords the only means of estab-

[1] Vanderbilt Clinic.

lishing a dietary that will certainly agree with the patient, and on which his health may be expected to improve, notwithstanding his possible distaste for some articles in his diet table. A patient's own sensation in regard to the degree of digestibility of certain foods is no guide at all in these cases. Having established a positive dietary, the next step is to give the patient exercise. As with this patient active exercise is out of the question at present, massage should be practised at first; and later, as his condition improves, walking, horse-back riding, etc., are to be advised.

With regard to drugs, most of these cases do well on some vegetable tonic before meals—the infusion of quassia, or of gentian, for example, either alone or with an alkali or an acid. As a rule, the alkali agrees best, but it is impossible to foretell with certainty which to use.

Phthisis.

Case II.—The patient is a woman, 23 years old, single, in previous good health; two months ago she was taken sick with fever, pain in the right side, and cough. On the first day she spat up blood, and also on the second day, but in less quantity; since then her expectoration has been whitish and without blood. She remained in bed for a day or two, her fever subsided somewhat and appeared chiefly in the evening; it was followed by sweating. She suffered from vomiting, which was due to the severity of her cough. Her feet and legs became somewhat swollen She lost strength, and twenty pounds in weight. Three of her family have died of consumption. To-day her temperature is 100°.2; the urine shows neither albumin nor casts, and her sputa, examined once, contained no bacilli. On physical examination of the lungs, there is found anteriorly good resonance and no rales. On the right side the breathing is somewhat rough, and the resonance above the clavicle is slightly high-pitched. Posteriorly, the left side is normal. On the right side, from the spine of the scapula down, there is dulness, amounting to flatness at the lowest part. Natural breathing is heard down to about the middle of the lung, and below this point it is bronchial in character. There is bronchophony from the spine of the scapula down, growing more and more marked toward the base of the lung.

A patient with this history and with these physical signs behind, and with no evidence of pulmonary disease in front of the chest, may be suffering from one of three diseases, namely, phthisis, broncho-pneumonia, or pleurisy with effusion. In the latter disease almost any physical signs may be found, and unless an aspirating needle is first introduced into the chest it will be impossible to make a positive diagnosis. This, then, would be the first thing to do. Moreover, the sputa should be examined daily for several days, to determine further the presence or absence of tubercle bacilli. But even if bacilli are not found, there is no certain evidence that tuberculosis does not exist. The longer it is searched for and not found, however, the less likely is the patient to be suffering from phthisis.

As for broncho-pneumonia, in the form presented here, it would be very rare in a person of the patient's age. The diagnosis of phthisis would, therefore, be the most plausible. If it is phthisis, the case is not so bad as it looks. This disease, to have made such advance in two months, would ordinarily prompt a bad prognosis. Not so, however, in those sub-acute cases beginning in the lower lobe of one lung, when the consolidation is confined to that lobe, as is the case with the present patient. It is quite possible to have a thorough recovery and for this reason: the tubercular part of the inflammation is small compared with the amount of the other inflammation—that associated with the infiltration of fibrin and pus. It is chiefly to this infiltration and not to tubercle that the consolidation is due.

Prof. Delafield says he has followed such patients for years, and has seen them recover from their phthisis and eventually die of some other disease; at the autopsy he has found that most of the lung had returned to its natural condition, and that only in small areas was there any result of the former lesion, and this was the site of the deposit of tubercle. This pathological condition, he says, also offers an explanation of the fact that bacilli are not found in the sputa.

With reference to the treatment, he said that a person in the condition of life of this patient, should be urged strongly to enter the hospital, and at first should be put to bed. The next consideration would be to feed her: milk, cream, beef teas—fluid diet—should be ordered, care being taken that it is retained by the stomach. Mild and persistent counter-irritation should be applied to the right side of the chest. This is all.

It is supposed, of course, that the diagnosis of phthisis has been confirmed, in speaking of the above treatment.

Foreign Correspondence.

LETTER FROM BERLIN.

(FROM OUR SPECIAL CORRESPONDENT.)

The Berlin Medical Society. — Leontiasis ossea. — Poisoning with Antifebrine. — Detection of Antifebrine in the Urine. — Prophylactic Use of Quinine in Malarial Diseases. — Most Satisfactory Medium of Antisepsis. — Peroxide of Hydrogen as an Antiseptic.

BERLIN, Oct. 19, 1888.

The Berlin Medical Society has again begun its weekly meetings, which enjoy a well-merited repute all over the professional world for the highly interesting and strictly scientific character of their discussions. Many of the members of the Society are well known in America, partly through their professional labors, and partly through their visit to the International Congress, in Washington. Besides Virchow, its President, the Society counts among its members men like Bardeleben, Ehrlich, Esmarch, Eulenburg, Fränkel, Gerhardt, Gusserow, Hahn, Henoch, Lewin, Leyden, Liebreich, and Waldeyer—a truly splendid array of medical celebrities.

Prof. Fränkel presented, at the first meeting of the Society, Oct. 10, a young girl with the rare affection of *Leontiasis ossea* The salient feature of this ailment is a peculiar and enormous hypertrophy of all the bones of the skull and the face. The girl, who was 12 years old, had up to 4 years of age always enjoyed good health; at that time she fell on the right side of her forehead, exactly on the frontal protuberance. Gradually, evidently as a result of this injury, two enormous prominences developed on her forehead, followed by a general hyperostosis of the head and face, giving the patient a very peculiar appearance. As the father had been specifically infected, it was thought that the syphilitic element had something to do with this affection. Virchow, however, rejected this supposition, and named the affection Leontiasis ossea, on account of its similarity to leontiasis in elephantiasis.

Those fond of prescribing the newest medicines will be pained to learn that Dr. Rohler has declared antifebrine to be not only not a harmless drug, as has been asserted, but, on the contrary, even capable of producing very serious poisoning. This information is the more worthy of note as antifebrine is quite a popular drug in headaches, especially in those of a neuralgic character. The victim was a young man, 19 years old, who had sent to a drug-store to obtain "something for a headache." The pharmacist sent him a white powder, with instructions to take one-half of it at once and the other half after a few hours, if no relief was obtained. The result was a frightful cyanosis, extending even over the point of the nose and the finger-nails, and a pulse of 152. The dangerous symptoms lasted for three days, when recovery began. It was learned that the patient had taken ninety grains of antifebrine, divided into two equal doses, in the course of four hours. The usual dose of antifebrine being about four grains, the man had taken two doses in quick succession, exceeding the usual amount nearly twenty-three times. This large dose has been exceeded only once, namely, by Dr. Simpson, of New York, who, for the sake of an experiment, took one hundred grains in seven single doses within two hours and a half. The cause of the cyanosis has been interpreted as either arterial spasm or as venous dilatation.

It will probably interest the readers of the Reporter to learn a ready method of determining the *Presence of Antifebrine in the Urine*. Antifebrine possessing a great power of resistance against chemical reagents, its determination consists in the recovery of aniline—a decomposition product of antifebrine—by means of the indophenol reaction. The urine is mixed with one-quarter of its volume of concentrated sulphuric acid, and boiled for some time. After cooling, one drop of liquid carbolic acid and a few drops of a solution of chloride of lime are added. In presence of antifebrine a red coloration appears which, by addition of ammonia, turns to a beautiful blue.

The possibility of preventing malarial diseases by the administration of quinine, is at present, in view of the colonial enterprises of the German Government, a question receiving considerable attention. The early observations of Dr. Schweinfurt, the noted African explorer, and of Prof. Hertz, of Amsterdam, on the prophylactic value of quinine in malarial diseases, have received a strong confirmation by the experience of Dr. Graeser, of Bonn, which has just been published. The author made five trips to Tandjong-Priok, the harbor of Batavia, Java, which is regarded as the most malarial point in the world, the entire place having been built by laborious dredging on the worst swamp imaginable. Ships stopping at that port frequently lose one-half of their crews;

of an English vessel, stopping there some time ago, the captain alone escaped the malarial infection. The results which Graeser obtained by large doses of quinine, mixed with the daily ration of gin, were such that the prophylactic power of quinine in malarial diseases can no longer be doubted. With the exception of some few cases, in which quinine proved utterly useless, the fever was effectually prevented by fifteen-grain doses of quinine, given every other day. Those moving into a malarial district will no doubt profit by this valuable observation of Graeser's.

In speaking of the papers read at the Cologne meeting of the German Medical Congress, the paper by Dr. Rotter, of Munich, on the *Most satisfactory Medium of Antisepsis*, was not referred to. Dr. Rotter emphasized the unequalled antiseptic virtues of corrosive sublimate and carbolic acid, but regretted that, even in the usually employed solutions, each often gave rise to serious constitutional troubles. An ideal antiseptic agent, in Rotter's view, would be one which, besides insuring prompt and complete antisepsis, could never produce poisoning. This problem Rotter appears to have successfully solved, not by a new drug, but by a combination of many antiseptic agents, each of which, in the quantity present, is absolutely harmless, while their union secures a perfect antisepsis. Rotter's solution contains, in a quart of water:

Corrosive sublimate	gr. ¾
(representing a solution of 1 to 20,000)	
Chloride of sodium	gr. iii ¾
Carbolic acid	gr. xxx
Chloride of zinc,	
Sulphocarbolate of zinc	āā gr. lxxx
Boric acid	gr. xlv
Salicylic acid	gr. ix
Thymol,	
Citric acid	āā gr. iss.

It will be seen from this formula that, with the exception of salicylic acid, all the drugs are represented only by one-tenth of their usually employed quantities. Citric acid serves to render the solution of chloride of zinc clear, while thymol serves to give the mixture a certain slight definite odor, in order to prevent its being drunk as water. The advantages of this antiseptic medium are said to be: (1) complete antisepsis; (2) absolute harmlessness; (3) ease and cheapness in obtaining it; (4) stability of solution and absence of color and unpleasant odor. Besides, the mixture can be prepared from the drugs by the mere aid of hydrant-water. Thus far the mixture has been tried in 27 surgical and 26 gynecological cases at the Munich Hospitals, and has given the most satisfactory results. In this connection it is proper to mention the assertion recently made by Dr. Tromp, that peroxide of hydrogen is an ideal antiseptic. In order to sterilize water, it is sufficient, according to his statement, to add one part of peroxide of hydrogen to 10,000 parts of water. To sterilize fifteen minims of water, it required: for 19,600 germs, the contact of one part of peroxide of hydrogen in fifty thousand parts of water for one day; for 34,000 germs, the contact of one part of peroxide of hydrogen to ten thousand parts of water for one day; for cholera bacilli, the contact of one part of peroxide of hydrogen in ten thousand parts of water for five hours; and for typhoid bacilli, the contact of one part of peroxide of hydrogen in five thousand parts of water for one day.

Peroxide of hydrogen is without odor or taste, and in the strength employed is quite harmless. The drug is cheap enough also, as one quart of a pure three per cent. solution costs only thirty cents. To sterilize ten quarts of a liquid, about one fluid ounce of this solution would be required. The advantages of Rotter's mixture, especially when made into pastilles, over Tromp's fluid, are very decided, as will readily be seen.

PERISCOPE.

Hot Baths in Chronic Synovitis.

Dr. G. Allexich, of Crema, states that he has used hot baths with good results in six cases of chronic synovitis of the knee, in some of which the affection was of many months' standing, and had resisted all ordinary treatment. Dr. Allexich makes his patients keep the knee immersed in hot water for half an hour at a time. The joint is placed in the water in a flexed condition, and the patient stands upright, resting the weight of his body on the sound limb and supporting himself with his hands on the backs of two chairs. When taken out of the bath, the knee is carefully dried and wrapped in cotton wool, the joint finally being carefully bandaged. For some days the patient should only go about on crutches. Dr. Allexich thinks that the virtue of various hot springs renowned for the cure of joint affections (such as Acqui, Abano, Viterbo, Ischia, etc.) consists not in their chemical composition, but in their temperature, and that equally good effects can be got at home by the simple means just described.—*British Medical Journal*, September 15, 1888.

Mortality of Pneumonia.

In the *University Medical Magazine*, Nov., 1888, Dr. William Osler discusses the mortality of pneumonia, and disputes the assertion of Dr. Hartshorne that the "mortality of pneumonia to-day is, under similar circumstances, more than twice as great as it was forty years ago." Dr. Osler shows that the statistics upon which Dr. Hartshorne relied to prove his proposition are susceptible of a different interpretation, and says that in our large city hospitals the death-rate in pneumonia always has been, and is likely to continue to be, very high, usually over 25 per cent., often reaching 40 or even 50 per cent Any slight increase in the death-rate which may have occurred at certain hospitals, he thinks may be reasonably attributed to the enormous increase in the pauper population of the large cities of this country during the past twenty years, which, of course, would cause a very great relative increase in the number of persons who live in conditions rendering them more susceptible to, and less able to withstand, such an affection as pneumonia.

With reference to the cause of death, he says:

"A good many complicated factors combine in an individual to cause death, but, studying the fatal cases of pneumonia as so many lessons from which to learn wisdom for the future, we may, I think, divide them into three groups: 1, those in which the death has resulted from such complications as gangrene, meningitis, ulcerative endocarditis—conditions at present beyond our art to remedy; 2, cases in which death has resulted from mechanical causes, over-distension and paralysis of the right heart; 3, the large group in which death has been due to failure of the general powers under the influence of the high fever, or of the specific poison, or of both combined."

With reference to treatment he says:

"We are likely to be deceived in our therapeutical conclusions unless we bear in mind the unquestionable fact that a very large proportion of all cases of simple acute pneumonia in healthy adults recover without the use of drugs. Careful nursing, feeding, local applications, keeping the bowels open and the skin active, meet the indications. Even in cases of great severity, with extensive involvement of the lung, we see the crisis occur normally under most adverse circumstances. Such a case occurred last session at the Philadelphia Hospital. The patient, admitted on the seventh day of the disease, had been up and about at his lodging and drinking heavily, and had had neither medical nor domestic care. Although delirious on admission, the crisis occurred on the morning of the eighth day and he entered upon a convalescence as satisfactory in every respect as if he had had the most approved antiphlogistic treatment.

"I have often puzzled over the cadavers of persons dead of pneumonia and asked why should this man have died? Too often the answer is the echo of the question. The cause is evident in many cases in the form of serious complications, such as endocarditis and meningitis. Some years ago I was struck in the post-mortem room, with the cases of young vigorous men, who had died with distended right hearts and systemic veins and extensive, though in some instances limited, areas of consolidation. It seemed as if the heart had failed in over-distension—asystole—and I determined, when the opportunity arose, not to let such cases die without a copious venesection. Clinically, I think, we see this condition in two different periods of the affection. There is an early cardiac embarrassment during the first few days of the disease, leading to slight cyanosis; and in a later period, at the 7th to the 10th day, we see with increasing anxiety the changing color, a dull suffusion, a deepening hue, then the marked cyanosis. Bleeding may be indicated at both these periods. In hospital practice we more commonly see the patients in the latter. For ten years past I have practised free bleeding to the amount of from 20 to 25 ounces in adults, and yet I have to confess to disappointment in my results. I have seen but one case recover after bleeding, out of twelve or fifteen. The cases of bleeding in the late stages have been uniformly fatal. I know it has often been performed with the patient *in extremis*, but it seems imperative to attempt to relieve an over-distended circulatory system. I know it does relieve in the cyanosis of cardiac dilatation from other causes, but in pneumonia there are doubtless conditions other than mechanical. In these cases the administration of oxygen or compressed air is often most serviceable. Complications carry off many, and direct cardiac failure not a few, but both together do not number the cases which we see gradually fail under the continued influence of the fever, the disturbed cardiac-respiratory mechanism and the poison. Here we are often baffled, but in this group we see repeatedly the beneficial effects of the timely use of cardiac and respiratory stimulants."

Experimental Excision of the Pancreas.

At a meeting of the Reale Accademia di Medicina of Turin, July 20, Dr. G. Martinotti described certain experiments he had made as to the effects of excision of the pancreas in dogs and cats. He had first removed the horizontal portion of the organ, and later on the vertical part, taking care to perform both operations at equal intervals of time after the animals had been fed and when the digestive function was in a state of inactivity. On comparing the two portions he found no evidence of compensatory hyperplasia in the one removed last. On removing the whole organ at once, however, except a tiny piece attached to the duodenum and in normal relation to the excretory duct, the stump examined after a certain time had elapsed presented different characteristics according to the extent to which it had been affected directly by the operation. The portion in immediate contact with the duodenum was unchanged, whilst the other extremity, which bore the amputation scar, showed signs of regeneration of the gland structure. There was no sign of increased activity in the liver or in Brunner's glands, which Landois is inclined to look upon as functionally analogous to the pancreas; on the other hand, the intestinal glands had evidently had an increased amount of work thrown upon them. At another meeting Dr. Martinotti exhibited the viscera of dogs from which he had removed the whole of the pancreas; the animals had been killed and dissected in the presence of several medical men the day before. In none was there a trace of peritonitis or of extravasated blood. In a dog on which the operation had been performed on June 23, the intestinal coils were healthy, and quite free from adhesions. A piece of pancreas, of the size of a small chestnut, was attached to the duodenum, with which it communicated by a special duct. In an animal operated on on June 25, and in another operated on on July 14, almost precisely similar conditions were found, the portion of pancreas in the former being of the size of a filbert, and in the latter of a lentil. The gastro-duodenal mucous membrane and the abdominal viscera were normal. On the other hand, in a puppy operated on July 15, which at first appeared to rally from the operation, but which afterward began to waste rapidly, no trace of pancreas was found; the duodenum was bent upon itself, and was adherent to the wound in the mesentery. Through the loop thus formed a knuckle of small gut was strangulated, and the lower part of the intestinal canal was entirely empty. Dr. Martinotti pointed out that the small portion of pancreas left in these cases was utterly insufficient to discharge the functions of the organ; he regarded them as proofs of attempted regeneration, as he was certain he had removed every particle of the gland, with the exception of a few acini, which were intimately connected with the walls of the duodenum, the bile-duct, and the blood-vessels. These acini had formed the starting-point of the regenerative action. He concludes that the pancreas can be removed (from dogs) without any ill effect, if the operation is done with proper precautions, especially as regards antiseptics. The greatest danger connected with the operation is the formation of adhesions, which may lead to strangulation of intestine.—*British Medical Journal*, September 15, 1888.

Transition of Benign Growths of the Larynx into Malignant.

It has been suggested that benign growths of the larynx are liable to become transformed into malignant tumors as a result of intra-laryngeal operations for their removal. This suggestion, if proved to be well founded, would do much to show that Van Bruns's introduction of intra-laryngeal operation for tumors was not the great improvement it has been held to be; but, on the contrary, a very mischievous procedure. The plan of collective investigation has been employed to throw light upon this subject by Dr. Semon, the editor of the *Internationales Centralblatt für Laryngologie*, &c., and in the July number of that journal the results of the inquiry are briefly given. These are so important that the profession should at once be made fully acquainted with them. Returns have been furnished by 107 observers, who have together recorded 10,747 cases of benign growths in the larynx and 1550 cases of malignant tumors. Of these 10,747 cases of benign growths, 8216 have been submitted to intra-laryngeal operation, and among this number there are 3382 cases of papilloma. An apparent transformation from benign into malignant growths has been noticed in thirty-two instances. Each one of these cases must be submitted to a very careful criticism, but, apart from that, as many as sixteen of the number are marked by those who record them as "doubtful," and they cannot therefore be used. It is quite open to question whether the remaining sixteen cases do not

include examples of "mixed" growths, and it is noteworthy that the tables include twelve cases not submitted to intra-laryngeal operation, in which a similar change in the nature of the growth was thought to be noticed. But putting aside this view altogether, we are met with this supposed change in one case out of every 513 cases thus treated. It must be at once admitted that if the operation had any appreciable influence in modifying the nature of a neoplasm, the proportion of cases in which it would be observed would be much greater than this. Considering the enormous advantages the intra-laryngeal method of operating possesses, it is a matter of considerable satisfaction that it is thus conclusively shown not to be attended with the grave danger that has been suggested in some quarters.—*Lancet*, July 7, 1888.

Codeine in Diabetes Insipidus.

Mr. Melville Jay, of Adelaide, South Australia (*The Australasian Med. Gazette*, vol. vii, No. 7, p. 166), believes that the following history will plainly prove that in some cases of polyuria codeine has a well-marked effect. A married woman, 37 years old, with no children, enjoyed good health up to twenty-six years of age. At that time she noticed a great increase in the amount of urine passed; either immediately preceding this event, or simultaneously with it, she suddenly ceased menstruating, and she has never had any return of her menses since that time. She was told that she was suffering from diabetes mellitus; the average daily amount of urine was thirty-two pints. She remained in this condition for two years, when no trace of sugar could be found in the urine. The daily excretion, however, has never fallen below fifteen pints, the average being from twenty to twenty-four pints without any return of sugar. Mr. Jay, on commencing attendance on the case, found twenty pints passed *per diem;* specific gravity 1003; no trace either of sugar or albumin; no casts; great tenderness of the posterior wall of the vagina and well-marked vaginismus, preventing intercourse for the past four years; uterus small, but healthy. She was inclined at times to be hysterical. He commenced by giving her a pill three times a day containing a quarter of a grain of codeine and half a grain of extract of nux vomica. On the second day the quantity of urine fell to nine and a half pints, on the third day to six pints, on the fourth day to four and a half pints. For two months after this she continued the same treatment, gradually increasing the amount of codeine to one grain three times a day; the daily amount of urine passed varied from four to six pints. She then ceased taking the medicine for a few days, whereupon the quantity rose to eight pints; but it was again reduced to five pints on returning to the codeine. The dose of the drug was purposely not increased to any great extent.—*Practitioner*, August, 1888.

Tubercular Peritonitis.

The *Archiv für klinische Chirurgie* publishes a paper by Dr. Kümmel, of Hamburg, on peritoneal tuberculosis. He says that many physicians even now believe that tubercular peritonitis is always a symptom of general tuberculosis. There are, however, many cases to prove that this form of tuberculosis is as purely a local affection as tubercular disease of the bones and joints, and that it is curable by surgical means. The earliest case on record was that operated on by Sir Spencer Wells in 1862, when he performed laparotomy with the view of removing an ovarian cyst. Finding that he had tubercle of the peritoneum to deal with, he drained it, and the patient was still in perfect health in 1887. Kümmel has collected forty cases of operation for tuberculous ascites. Two of the patients (both operated on by Naumann) died of pyæmia; thirty-eight recovered from the operation; only three of these died afterward of phthisis. Thirty-five remained healthy up to the date of the report; they had increased in weight, and their health was excellent; even the symptoms of pulmonary phthisis disappeared in some cases. Thirty-nine patients were of the female sex. In each case an erroneous diagnosis was the cause of the operation. The disease was always supposed to be a tumor of the ovary, or some other abdominal tumor with liquid contents. Only once the ascites was found in the course of an operation for ileus. The symptoms of the disease are those of circumscribed ascites, but the affection may also simulate tumors of various kinds, for, by adhesions of the intestines, there are formed pockets and cavities, receptacles of pus, serum, etc. The favorable results of the operation justify laparotomy for peritoneal tuberculosis in every case in which it is possible to recognize the affection. Even the existence of pulmonary phthisis does not contra-indicate the operation.—*British Med. Journal*, July 7, 1888.

Double Aneurism of the Ascending Aorta.

At the meeting of the Baltimore Academy of Medicine, Feb. 21, 1888, Dr. Thomas F. Murdoch reported the following case of double aneurism of the ascending aorta, and said that on February 13, at 8 P. M., he was summoned to see Mr. B., and found him complaining of nausea, great pain in the epigastric region (which was very sensitive to pressure), eructating great quantities of wind, and his heart beating so tumultuously that it was impossible to determine if there was any disease of the valves. The patient said that he had had dinner at 3 o'clock, consisting of a beefsteak and a potato, and shortly afterward was seized with nausea, pain in the stomach, and tumultuous action of his heart, which obliged him to go home, but he did not send for Dr. Murdoch until the hour above named. Dr. Murdoch prescribed an antispasmodic mixture and after giving two doses, he left the patient somewhat relieved and ordered a dose of castor oil to be taken in the morning. He was disposed to give him an emetic, but the patient said that he was never able to vomit. Dr. Murdoch was again called at 1 A. M. the next day, and found the patient still suffering; he ordered an enema, and at his own suggestion gave him half a tumbler of Hunyadi water. The enema brought away some hardened feces, and, at the same time, the patient vomited some fluid, but nothing that he had eaten. He expressed himself as feeling much better than he had done since he was first taken sick. Dr. Murdoch remained with him until 4 A. M., and left him comfortable, although his heart was acting tumultuously.

Dr. Salzer met Dr. Murdoch in consultation at 9 A. M. Dr. Salzer had attended Mr. B. last summer at Bedford Springs. He agreed with Dr. Murdoch that the action of the patient's heart was sympathetic and said that he had frequently examined both the heart and also the urine, and he was certain there was no disease of either heart or kidneys. Dr. Salzer treated the patient for gastric trouble. After much consideration they determined to give him 20 grains of ipecac in compressed pills, which instead of vomiting him, had the most soothing effect, and he got some sleep, the first he had had. After fifteen minutes, the ipecac was repeated, and he slept for nearly two hours, waking occasionally. Dr. Salzer left at 11.30, considering him much better. Dr. Murdoch remained until 12.30, thinking then that he could leave him for an hour or so, but he had not been away more than thirty minutes when the patient expired suddenly.

At the autopsy made by Dr. Councilman, both lungs were found to be œdematous. In the left pleural cavity was about one ounce of clear serum. The entire heart was enlarged, both ventricles, especially the left, somewhat dilated. The wall of the left ventricle slightly thickened. The muscular tissue of heart flabby. All the valves of the heart were normal. The aorta atheromatous in its entire extent. In the aorta just above the aortic valves were two aneurisms, one opening into the sinus of Valsalva behind the right anterior valve and one behind the posterior valve. The one to the right was of the size of a black walnut, its opening into the aorta about three-fourths of an inch in diameter. The aneurism opening behind the posterior valve was not larger than a small hazel-nut.

In the wall of the right auricle there was an area about one inch in diameter where the wall was thin, anæmic and in the middle of this a ragged opening the size of a No. 14 catheter which passed directly into the larger aneurism. Both aneurisms contained red coagula.

Case of Suicide, with Numerous Wounds.

In the *Prager med. Wochenschrift,* March, 1888, Prof. Von Moscha communicates the case of a man, 51 years of age, who was admitted into an asylum on account of insanity, and after an interval of two months had apparently so far recovered as to be entrusted with a knife for the purpose of cutting an apple. In the night following he was found covered with numberless wounds, from which blood was abundantly flowing, and died the succeeding evening. Amongst other wounds, more than 200 were found on the left half of the chest, 50 on the inner side of the left forearm, and 28 small wounds on the inner side of the right forearm. The left radial and ulnar arteries were divided. On section, six of the wounds on the left side of the chest were found to have penetrated the thorax through the intercostal muscles; the ribs and sternum were not injured. Blood was found in the left pleural cavity, compressing the lung, which was otherwise uninjured. In the anterior mediastinum and on the fat deposited on the pericardium, blood was effused; the heart and pericardium were uninjured. The wounds were made with a small-bladed knife; death was caused by hemorrhage.—*Medical Chronicle,* September, 1888.

Cardiac Complications in Rheumatic Fever.

In a communication to the *Practitioner*, August, 1888, on the form and frequency of cardiac complications in rheumatic fever, Dr. Samuel West says that during the six years that he was Medical Registrar at St. Bartholomew's Hospital, he collected a number of statistics bearing on the subject of rheumatic fever. He gives the results of these in the present paper.

The cases were taken without selection from the ordinary practice of the hospital, and therefore had been treated in various ways. To most salicylate of sodium in frequent doses had been given until the pain was lost, the doses being then reduced. All were placed on low diet, purges administered when necessary, and absolute rest enforced until the pains had been absent for some days; if an increase in diet was then tolerated without return of pain the patient was allowed to get up. He believes that, speaking generally, the patients were kept in bed longer than is usual in many other places.

Accompanying his paper are tables showing the distribution of the cases at the different ages and in the different attacks. The most important part of the statistics, however, deals with the frequency of cardiac complications and their nature at the different ages, in the two sexes, and in the different attacks.

The total number of cases under observation during the six years was 1,137; and as only 15,552 cases of all kinds were admitted during the same period, it is seen that rheumatic fever must be a very common disease, forming, according to these statistics, 7.31 per cent. of all cases. The only other diseases which approached it in percentage frequency were typhoid fever, pneumonia, and phthisis. Death occurred only fifteen times in the 1,137 cases, giving a rate of 1.32 per cent. Of the fifteen deaths, no less than nine occurred in children under ten years of age, so that the mortality in adults must be much lower, say about 0.5 per cent. The cause of death, he says, was found in all cases. There was only one instance of hyperpyrexia, and that recovered after cold bathing.

Out of the 1,137 cases, 619 were in males, and 518 in females, or nearly in the ratio of six males to five females. As regards age, 61.4 per cent. of the cases occurred between the ages of fifteen and thirty years. The average age of the patients at the time of the first attack was in males 22.43, and in females 22.16 years.

Of the whole number of cases (1,137) 70 86 per cent. developed cardiac complications. In this estimate Dr. West included only those who left the hospital with distinct murmurs. When the figures for the two sexes are examined, it will be seen that although the number of cases of rheumatic fever is larger in males, the percentage of heart disease is smaller—64.16 in males as against 77.56 in females In other words, the risk of cardiac complication is greater in females than in males.

After giving the relative frequency with which the different valves and the pericardium are affected, Dr. West says, in conclusion, that the conviction has been growing in his mind that heart disease is an almost essential part of rheumatic fever.

Scarlatinal Otitis Media.

Voss (*Archiv für Orenheilkunde*, xxvi, S. 231) calls attention to a late form of otitis media occurring in the course of scarlet fever, which depends upon the nephritis accompanying the fever. With the diminution of the secretion of urine and the accompanying fever, also frequently preceding these, there occurs difficulty in hearing, with pain in one or both ears. Then come the physical signs of redness of the mucous membrane of the throat, "hyperemia of the auditory canal, in which the drum-membrane participates but little or not at all, but no exudate." If an increase in the quantity of urine occurs, all these symptoms may disappear. If, on the other hand, it remains very small, then quickly occur exudation, redness and swelling of the drum-membrane, perforation of the latter, and at first a serous followed by a sero-purulent discharge. The secretion, which is very copious at first, becomes less but continues, and is sometimes a direct measure of the degree of albuminuria present. If the secretion is scanty, an examination of the urine shows diminution of the albumin and increase in the amount of urine, and *vice versâ*. Increase in the secretion corresponding to an increase in the quantity of albumin and inversely proportional to the quantity of urine, is more striking to the eye. If the albuminuria disappears quickly, the otitis media lasts ordinarily about one or two weeks. Hearing becomes normal. If the albuminuria is protracted in its duration, the otitis may heal first. Treatment must be directed to the nephritis as well as to the ear-disease. —*Centralblatt f. d. med. Wissenschaften*, September 1, 1888.

Tissue Changes in the Human Fœtus.

A paper by Dr. Dührssen, of Berlin, in the *Archiv für Gynäkol.* (Bd. xxxii, 4, 3), gives the result of some recent investigations into the subject. After giving benzoate of soda and glycocol, as Gusserow had previously done, to women in labor, he was able to confirm his chief's investigations as to the presence of hippuric acid in the urine of the child when born and likewise in the liquor amnii. In six cases, however, he found benzoic acid but no hippuric acid in the placentæ. The statement of Ahlfeld, therefore, that the benzoic acid became converted into hippuric acid before it reached the fœtus, was proved to be incorrect. In three of the cases, hippuric acid was also found in the urine; it must therefore have been formed in the fœtus from benzoic acid and glycocol. Hippuric acid was not so constantly met with in the liquor amnii; but its presence there proved urination on the part of the fœtus into it. As it was not constantly present, however, the author assumes that urination does not take place continuously. He believes that the kidneys are active as early as the second half of pregnancy, that the liquor amnii is a secretion from the kidneys of the fœtus and not a nutrient fluid. From the absence of benzoic acid in the liquor, it follows that there is no transudation into it through the maternal decidua in the latter half of pregnancy. Another point demonstrated by the investigation is that the liquor amnii is not in part a transudation from the vessels of the cord, otherwise the benzoic acid which reaches the fœtal circulation as such would also be met with in it. A proof of the activity of fœtal tissue changes, if such were needed, lies in the fact that the whole of the hippuric acid was excreted from the fœtal kidneys within twenty hours of the administration of the benzoic acid to the mother, and this shows also that labor had no influence in retarding the changes. If the benzoic acid was given twenty hours before the birth of the child, its urine showed no trace of hippuric acid; it had all been emptied into the liquor amnii before the completion of the act of parturition. The benzoic acid appeared in the placenta within three-quarters of an hour of its administration. Reckoning the quantity of albumin passing to the fœtus from the maternal blood by the proportion of the benzoic acid given to the mother that passed through the placenta, it was estimated that it received about 80 grains daily.—*Medical Press and Circular*, September 12, 1888.

Primary Tubercular Tumor of the Larynx.

Dehio (*St. Petersburger med. Wochenschrift*, No. 16, 1888) reports a case of primary tubercular tumor of the larynx occurring in a man 41 years old, who had no recognizable disease of the lung. The tumor arose from the left ventricular band, had a broad base and included nearly the whole length of the band. The tumor reached to the median line of the chink of the glottis, covering in quiet breathing nearly the whole vocal cord; it was of a bright green color and presented a flat-backed, irregular surface, whose separate rounded elevations were from the size of a pin-head to that of a millet seed. There was no ulceration. All the rest of the mucous membrane was swollen and reddened; the right ventricular band a good deal thickened. Dehio thought the possibility of a malignant growth was not excluded, and for this reason the larynx was split and the tumor extirpated by Wahl. The tumor was then found to be made up of thick layers of tubercle nodules closely set. Following the operation, remittent fever, cough and thoracic pain developed; emaciation increased, profuse night-sweats occurred, and the patient died seven weeks later with marked symptoms of tuberculosis of the lungs.

W. Lublinski remarks upon this case that infiltrations of the larynx of this kind, with punctiform infiltration, are not so rare, and in his opinion are not to be reckoned among the tuberculous tumors of the larynx first observed by Schnitzler and Mackenzie. —*Centralblatt f. d. med. Wissenschaften*, September 1, 1888.

Hydrastis Canadensis in Vesical Hæmaturia.

In the Moscow monthly *Novosti Terapii*, May, 1888, p. 192, Dr. F. Stroinovsky draws attention to a powerful contracting action of hydrastis Canadensis on the blood-vessels of the bladder. For the sake of illustration, he adduces a striking case of intense vesical hæmaturia in an infant seven days old, in which the bleeding was completely and permanently arrested by four doses of the following mixture:

℞ Extr. hydrastis Canadensis fluidi . gtt. vi
Emulsionis amygdalæ dulc. . . . f℥i
M. D. S. A teaspoonful every hour.

A warming compress over the vesical region was also used.

Rhus Aromatica in Enuresis Nocturna.

In the Moscow bi-weekly *Meditzinskoïe Obozrenië*, No. 7, 1888, p. 709, Dr. N. Gündobin, of Professor N. A. Tolsky's pediatric clinic, writes that following the recommendations of Ellis, Max and Unna, he tried fluid extract of *Rhus aromatica* in 18 cases of enuresis nocturna, mostly of an idiopathic or neurotic origin, the patients being boys and girls from four to twelve years of age. The dose varied from six to twenty drops twice daily. In twelve of eighteen cases, most brilliant results were obtained, a permanent cure ensuing after the treatment of from seven to twenty-one days' duration. No relapses occurred in any of the patients, some of whom were seen again by Dr. Gündobin about a year after their recovery. In the remaining six cases the drug proved either wholly inactive, or brought about only a slight decrease in frequency of the patient's involuntary micturition. The unsuccessful cases included two of a post-scarlatinal enuresis nocturna; one of organic disease of the spinal cord (with enuresis diurna and nocturna), etc.; in short, in this category of cases the affection was of a secondary and not of an idiopathic origin. Dr. Gündobin never saw any untoward accessory effects from the drug. Children are said to take it quite readily.

Rare Ectopia of the Heart.

This anomaly was observed by M. Poteïénko (*Vratch*) in a female child several hours after its death. The heart, which was as large as a hen's egg and absolutely without pericardium, was outside the thoracic cage upon the anterior wall of the latter, and a little to the left. The apex of the heart was directed upward, the base downward. The thorax was closed in all directions with the exception of an opening about the size of a ten-cent piece, through which the great vessels passed. This opening, which was so completely filled by the large vessels that it was impossible to introduce the finest probe, was near the anterior insertion of the diaphragm, under the inferior border of the cartilage common to the seventh, eighth, ninth and tenth ribs, a little toward the left of the median line. The parents of the child unfortunately refused to permit an autopsy. According to the testimony of the priest, the child was born living, and lived for about an hour. The heart could be seen to contract rhythmically.—*Bulletin Médical*, August 29, 1888.

Frequent Micturition in Women.

Alexander Duke says this distressing complaint is commonly met with among women suffering from internal disease, and the diagnosis of the cause is sometimes by no means easy. In cases in which, after careful examination, the urine itself as a source of irritation can be excluded and the uterine symptoms complained of are not sufficient by reflex action to account for the continual annoyance, he has remarked in a great number of these cases an unnatural appearance of the meatus urinarius, the opening being much smaller and rounder, reminding one somewhat of the pin-hole os seen in conjunction with conical cervix uteri.

This description of case he says is comparatively easily cured by forcible dilatation of the meatus or urethral canal, but he has noticed a rather curious phenomenon to occur during the process, that is, the escape of a considerable quantity of urine when the blades of the dilator are freely opened (and this after the bladder had been but a few moments before to all appearance fully emptied by the catheter), the amount of urine escaping being fully equal in some cases to that previously removed.

Dilatation of the urethral canal he finds the most useful treatment in all cases in which the urine is normal, and spasm and irritability are complained of; but when there is a manifest want of tone in the bladder, a mixture containing tinct. of the chloride of iron, cantharides, and nux vomica has always given him satisfactory results. A blister over the sacrum has been found useful in exceptional cases. The galvanic battery he uses as a *dernier ressort*, and has had most satisfactory results in some apparently hopeless cases, one patient having worn a urinal for more than five years, night and day, previous to his seeing her.

Paralysis of Motor Bulbar Nerves in Graves' Disease.

G. Ballet (*Gazette Hebdomadaire*, No. 9, 1888) states that a man 34 years old developed all the symptoms of Graves' disease as the result of violent excitement caused by a fall into the sea. At the same time occurred hysterical symptoms—left-sided anæsthesia, diminution of the sensibility of the right half of the body, globus hystericus, etc. Subsequently the patient developed a complete exterior ophthalmoplegia and a bilateral facial palsy. Ballet thinks it is more than probable that the symptoms in this and also in other cases of Graves' disease are to be referred to a bulbar origin.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

TESTING HYPNOTICS.

One of the most interesting and instructive papers which has appeared in the medical journals for some time is that of Dr. Ottomar Rosenbach, of Breslau, in the *Berliner klin. Wochenschrift*, June 11, 1888, entitled: "Remarks on the Method of Testing Hypnotics." The greatest merit of this paper is that it discusses in an admirable way the ideas which should govern experiments in regard to the therapeutic value of hypnotics in general, and that it suggests thoughts which would be valuable if applied to similar experiments in regard to any medicament. So far as hypnotics are concerned, Rosenbach remarks that we must never fail to recognize the fact that loss of sleep may depend upon peculiarities of the individual, as well as upon peculiarities of his ailment. A careful study of these two elements in any case of sleeplessness, if successful, would furnish a clear indication as to the particular hypnotic which should be administered, while neglect of such a study would leave the physician to blind and often fruitless attempts to find out what his patient required.

One advantage of such a method as Rosenbach recommends is that it would often lead to the use of comparatively mild and relatively innocent hypnotics, instead of those more energetic ones which are likely to be followed by disagreeable after-effects. Of these, morphia furnishes perhaps the most striking illustration, and it is probably safe to say that the half is not known of the danger of an unwise use of this drug. The same may be said in regard to chloral, and it is one of the signs of a progressive spirit in the medical profession that unceasing effort is directed toward finding remedies which shall secure sleep in cases to which these remedies are but imperfectly applicable.

Among the best of those recently proposed are amylene hydrate and sulphonal, and we have acquainted the readers of the REPORTER, from time to time, with the results claimed for both of these hypnotics. The latest claimant for professional acceptance is sulphonal, which has been very strongly recommended, especially by Rosenbach, as a perfectly safe, simple, and efficient hypnotic for insomnia. It has not produced equally good results in the hands of all who have used it; but we incline to the opinion that if it were employed with the careful study of the peculiarities of the disease and of the patient which Rosenbach advises, it would not prove disappointing. Some of the disappointments which have been reported may have been attributable to the use of sulphonal in cases to which it was not suited. Others may

have been due to the administration of an impure or imperfect article. But no one could read the statements of Rosenbach as to the method he has employed in testing sulphonal without being convinced that it has very valuable properties as a hypnotic for cases of sleeplessness not due to pain or to extreme nervous excitement. Its best field of operation seems to us to be in cases of pure insomnia, and we would advise the readers of the REPORTER to give it a fair trial in cases of this sort, and to communicate their experience to their professional brethren.

THE CHAIR OF SURGERY IN THE UNIVERSITY OF PENNSYLVANIA.

Within a very short time of the announcement that Dr. William Osler had resigned the chair of Clinical Medicine at the University of Pennsylvania, the friends of this institution have been pained to hear that Dr. D. Hayes Agnew had resigned the chair of Surgery. This news was not exactly correct; but Professor Agnew has indicated a desire to lay down the duties of his office as soon as his colleagues and the Trustees of the University will consent to part with him. The pressure of his very large private practice has for some time made it very difficult for him to meet his classes regularly, and he has been able to do this only at a cost of great personal sacrifice.

The prospect of losing the benefit of Dr. Agnew's services as a teacher is one which the friends of the University must regard with deep regret, and we sincerely hope that this loss will be deferred as long as may be consistent with his personal comfort. But the fact that he seriously contemplates resigning his chair necessarily brings forward the question of choosing his successor. Already the names of a number of surgeons have been mentioned as candidates for the position, and the selection from them will undoubtedly be made only after a very active canvass.

The choice will call for the exercise of great judgment on part of the Trustees of the University, because Dr. Agnew's skill as a surgeon, ability as a teacher, and unimpeached integrity as a man have made an ideal which ought to be maintained in his successor. Whenever the time for making this choice shall arrive, we trust that it will fall upon a man who will add new lustre to the University and contribute to its further advance in the career of honor and usefulness which it has so long pursued.

CHYLURIA.

The nature of Chyluria is still so little understood, that every intelligent study of this disorder is deserving of attention. Such a study was made by the late Dr. Goltze, of Jena, and is described in a little book published last year and reviewed in the *Berliner klin. Wochenschrift*, June 11, 1888. It contains an account of the history of a patient who was for a long time under observation in the medical clinic of Jena—a hysterical woman, twenty-one years old, who had had repeated attacks of rheumatism. The most striking feature of the case was a progressive diminution of the area of liver-dullness. The proportion of fat in the urine was nearly constant, and the filtrate was usually clear. Dr. Goltze was led, by his study of this case, to the conclusion that, in chyluria, the urine is excreted in the characteristic condition, and that the condition is not due to a mixture of chyle or lymph with the urine after the latter is excreted in the kidneys.

Careful observation of the patient under varying conditions of diet led Dr. Goltze to believe that the alterations in the urine were not dependent upon the amount of fat ingested, but that they did bear a constant relation to the amount of albuminous food eaten, and that a vegetable diet was more suitable for patients with this disease.

This practical conclusion is, perhaps, the most important one suggested by this case; although it is interesting to note, and it may be profitable to follow up, the theory that chyluria is dependent upon a disease or disorder of the liver. There is much force

in the arguments with which Dr. Goltze supports this opinion, and we commend it, as well as his suggestion as to the diet of patients with chyluria, to the attention of our readers.

LAPAROTOMY FOR GUNSHOT WOUNDS.

As we have already stated in the REPORTER, May 12, p. 611, quite an animated discussion has recently taken place in Paris in regard to the propriety of immediate and exploratory laparotomy in cases of gunshot—that is to say, pistol-shot—wound of the abdomen. Dr. Paul Reclus has strongly opposed the performance of laparotomy before there are distinct evidences of perforation of the bowel or of peritonitis. His opinion rests largely upon his experience in a few cases, in which expectant treatment was followed by recovery. On the other hand, he cites only four cases of immediate laparotomy for shot-wound of the abdomen as having been performed in France.

It seems strange to find so great a difference between the practice of French and American surgeons as is shown in this matter. Here immediate laparotomy may be said to be the rule in these cases, and to be no longer a rare operation. This is due to the fact that we have now a great many surgeons who have no fear of the peritoneum, and who know how to conduct operations on the contents of the abdomen in such a way that the mere operation adds very little indeed to the risks the patient runs.

With abdominal surgery at such a point of development as it is in Philadelphia, for example, there seems no good reason why penetrating wounds of the abdomen should not be followed by immediate laparotomy, with all the advantages this can bring of accuracy in diagnosis and effectiveness in treatment.

Of course this does not mean that everybody who sees a case of this kind would be justified in doing laparotomy; but it does mean that the operation of laparotomy, properly performed, should be regarded as a relatively safe and absolutely useful procedure in the management of cases of penetrating wound of the abdomen.

TREATMENT OF PLACENTA PREVIA.

In an article in the REPORTER of May 19, 1888, Dr. Noble discusses the methods of treatment that have been employed in treating placenta previa since the days of Paul Portal, who was the first to publish the real nature of this complication of pregnancy and labor. There are many points of interest in this historical summary. Not the least interesting is the fact that Portal himself employed a very excellent plan of treatment, with good results. Indeed, had he but known and used the method of combined version, instead of internal podalic version, his method would have been hard to improve upon; for he recognized the importance of delivering the woman as soon as a diagnosis of placenta previa was established, and also the need of gentleness in extracting the fœtus. The most gratifying feature of the article is the evidence of the great reduction in the maternal mortality brought about by methods of treatment introduced during the last forty years. Instead of a maternal mortality of thirty or forty per cent., operators can show more than ninety-five per cent. of mothers saved.

In view of the present knowledge of this subject, it is painfully evident that many lives have been sacrificed to the application of false theories. *Accouchement forcé* has sent many women to their graves, from shock, rupture of the uterus, or post partum hemorrhage. The dread of undertaking premature delivery, for fear the cervix should dilate with difficulty, or version be rendered difficult, which so long influenced the profession, undoubtedly was the cause of death to many mothers and to more children. The mother might not die after any of the hemorrhages which occurred during pregnancy, but she was so weakened thereby as to be unable to withstand the shock of

the labor and attendant hemorrhage; or, escaping death from these causes, she fell an easy prey to septicæmia. The results of the practice of inducing premature labor, popularized by Greenhalgh and Thomas, have amply disproved the older views. The too-prolonged use of the tampon in unsuitable cases, without antiseptic precautions, has unquestionably swelled the death-list. Someone has remarked that the tampon gives a false sense of security. The abuse of ergot and early rupture of the membranes have also been the cause of death in some cases. The failure to employ the Braxton-Hicks method of combined version, instead of internal podalic version, is still the cause of fatal results. Time and blood are wasted in waiting for the os to dilate sufficiently to introduce the hand without violence into the uterus, when one or two fingers only are necessary, and these can almost always be introduced, even before labor is begun.

Except in cases of lateral or marginal placenta previa, or where hemorrhage is insignificant, the method of Hicks or that of Murphy should be employed. Hicks's method, in ninety-three cases, saved ninety-two mothers. Murphy lost no mothers in twenty-three cases. Each method has, theoretically, some advantages to the fœtus. By the method of Hicks, the advantages, without the disadvantages, of early rupture of the membranes are obtained. The uterus is allowed to contract down, and thus lessen hemorrhage; and, except in complete placenta previa, the placenta can ascend with the dilating lower uterine segment, thus preventing a certain amount of utero-placental separation, and consequent interference with fœtal blood-changes On the other hand, Murphy's method allows of quicker labor without endangering the mother, which counterbalances the deliberate partial separation of the placenta. Murphy's method seems to include the good features of that of Barnes. Unfortunately for the infant, no plan of treatment seems materially to improve its chances.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

CHEMICAL EXPERIMENTS FOR MEDICAL STUDENTS, ARRANGED AFTER BEILSTEIN. By W. S. Christopher, M.D., Demonstrator of Chemistry, Medical College of Ohio, Cincinnati. 16mo, pp. 84. Cincinnati: Robert Clarke & Co., 1888. Price, $1.00.

The second edition—for the sale of the book will probably demand one—of this manual for students will be better than the first, as there are numerous errata noticed at the beginning of the work, and other mistakes and discrepancies are to be found in the text.

The general plan and many of the tests of this excellent handbook have been taken from the works of Beilstein, the celebrated German physiological chemist. Most of it meets with our hearty approval, but one or two points where amendment would be advantageous may be pointed out in the interest of the author as well as of his readers. Some of the reactions given would be better understood by the student if they were more fully explained, as when magnesian fluid is used in testing for phosphoric acid; others might easily, we think, be written more simply, as the reaction No. 2 under arsenic; and one or two of the reactions described are actually wrong, as for example that in Reinsch's (not *Reinch's*) test for arsenic. Ammonium hydro-sulphide is erroneously called ammonium sulphide, and objection might also be raised to the word alkalinize. Excepting in these points, the book has much to commend it to favor. The tests are, as a rule, well chosen, and the laboratory application of preparing and using them is in some cases exceptionally good. The book is well calculated to meet the want it was intended to supply, and may be heartily commended to the notice of our readers.

A MANUAL OF GENERAL PATHOLOGY. By Joseph Frank Payne, M.D., Oxon., F.R.C.P., Physician and Joint-Lecturer on Pathological Anatomy at St. Thomas's Hospital, etc., with one hundred and fifty illustrations. Large 8vo, pp. 528. Philadelphia: Lea Brothers & Co., 1888. Price $3.50.

The preface to this very handsome book states that it is intended to provide medical students with an introduction to general pathology; but it does more than that, for it covers a wide range of subjects in a manner which carries it far beyond what might be expected of a mere introduction to this important study. It is not so full in this description of pathological histology as some of the larger works on pathology which are now accessible, but it devotes more attention to the study of etiology; and for this reason is more adapted to the needs of the general practitioner than to those of the special student of pathology. This makes the book of peculiar value to men engaged in the practice of medicine, but, at the same time, its excellent arrangement of subjects, clearness of description, and admirable illustrations will commend it, we believe, to all who wish a trustworthy and interesting guide in the study of general pathology. It is the result of careful personal observation and thorough familiarity with the work of other laborers in the same field of investigation, and may be heartily commended to the attention of our readers.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

Section of Contractured Tissues Essential Before Mechanical Treatment can be Effectual. By Lewis A. Sayre, M.D., New York. From the *Transactions of the Ninth International Medical Congress.* Vol. III. 14 pages.

On the Deleterious Results of a Narrow Prepuce and Preputial Adhesions. By Lewis A. Sayre, M.D., New York. From the *Transactions of the Ninth International Medical Congress.* Vol. III. 16 pages.

144. Address in Medicine. By Edward R. Mayer, M.D., Wilkes-Barre, Pa. From the *Transactions of the Medical Society of Pennsylvania*, June, 1888. 29 pages.

145. A Study of the Arteries and Veins in Bright's Disease. By Arthur V. Meigs, M.D., Philadelphia. From the *Medical Record*, July 7, 1888. 31 pages.

146. Biennial Report of the President of the Board of Health to the Legislature of the Hawaiian Kingdom. Session of 1888. Honolulu: 1888. 87 pages.

147. A Case of Leucæmic Retinitis. By George E. De Schweinitz, Philadelphia. From the *American Journal of Ophthalmology*, April, 1888. 4 pages.

148. Some Cases of Habit Chorea, and their Treatment. By G. E. De Schweinitz, M.D., Philadelphia. From the *Transactions of the Philadelphia County Medical Society*, May 9, 1888. 8 pages.

—In this pamphlet, which is abundantly illustrated, Dr. Sayre describes what he means by "contractured" tissues as compared with what he designates as "contracted" tissues. For the former he believes that complete division must precede any attempt to correct deformity by means of mechanical appliances. The results obtainable by the method he advocates are illustrated by the description of a number of cases in which he practiced it, and the pamphlet concludes with a report of the discussion which followed Dr. Sayre's address.

—This pamphlet gives the views of Dr. Sayre upon a subject to which he called the attention of the profession nearly twenty years ago, and which led to a rather free and indiscriminate employment of the operation of circumcision in a variety of neuroses in young boys Dr. Sayre does not approve of this excess, and advises slitting the prepuce and liberating the glans rather than circumcision.

In the discussion which followed his paper, Dr. Willard, of Philadelphia, advocated stretching and retracting the prepuce as preferable to any cutting operation, and his remarks form an exceedingly valuable supplement to those of Dr. Sayre. The whole pamphlet is very interesting and instructive reading.

144. Dr. Mayer's address contains an interesting and instructive general review of the present state of medical science, but one which is hard to describe, because it covers so much ground. Those who read it will find much that will entertain them, and much which will prove suggestive in the discharge of their professional duties; for he presents many important scientific truths in an unusually attractive manner.

145. Dr. Meigs's paper, which is illustrated with thirteen representations of the microscopical appearances of the minute blood-vessels in Bright's disease, contains a scholarly discussion of the nature of this complex malady. With due deference to the opinions of other investigators, and a due appreciation of the difficulty of drawing reliable conclusions from the most carefully conducted observations, Dr. Meigs states his own opinion that the most characteristic pathological changes in Bright's disease are found in the intima of the arterioles; and he is not disposed to attribute so much importance to the alterations found in the nerves, as Dr. DaCosta does, as stated in his pamphlet which we noticed in the Reporter, Oct. 27, p. 539, 1888. We heartily commend his paper to the attention of our readers, as a very valuable contribution to the study of a disease which is still unfortunately very obscure.

146. Dr. N. B. Emerson, in this Report, presents an exceedingly interesting account of the state of public health in the Sandwich Islands, which contains, among other things, very valuable contributions to our knowledge of leprosy. It is important to note the opinion of one who has such unusual opportunities for observation that leprosy is a contagious disease, and that it is practically incurable by medication. We cannot do more than indicate the interesting character of this report, and commend it especially to the attention of those who are interested in leprosy, as furnishing valuable data for forming an opinion in regard to this disease.

147. Dr. De Schweinitz describes a case of retinitis due to splenic leucocythæmia which was under careful observation for some time at the Hospital of the University of Pennsylvania. The results of the observations made then are well detailed, and the account is a useful addition to the literature of the subject.

148. Dr. De Schweinitz, in this paper, gives an account of the history of seven cases of that form of chorea to which Dr. Weir Mitchell has applied the descriptive term "habit chorea." They admirably illustrate the advantage of correcting errors of refraction in such cases, and furnish Dr. De Schweinitz an opportunity to call attention to the importance of noticing and curing disorders of the conjunctiva when these are found associated with chorea.

Literary Notes.

In January, 1889, there will be issued from the press of A. L. Chatterton & Co., New York, a new quarterly, entitled "*The Journal of Ophthalmology, Otology and Laryngology.*" It will be edited by George S. Norton, M.D., assisted by Charles Deady, M.D. Subscription price $3.00 a year. The Journal will be devoted to original articles upon the three specialties, and, in addition to original papers by prominent writers, the material found at the N. Y. Ophthalmological Hospital will be utilized.

The University Magazine is the name of a monthly medical magazine the first number of which is dated October, 1888 This number contains sixty-eight pages, the size of that of the Reporter, with original articles from men connected with the University of Pennsylvania, and news of the various medical departments of this institution. It is likely to prove very interesting to all who have an interest in the University of Pennsylvania, and, if the promise of the first number be borne out, it will be valuable to all who are interested in the medical sciences. The price is $2.00 a year, in advance.

CORRESPONDENCE.

The Prevention of Conception.

TO THE EDITOR.

Sir: My attention has been arrested by your appeal to physicians to interest themselves in the question of the prevention of conception in the married state. You say very justly that they are often appealed to in private, but refrain from discussing the subject in the medical journals from deference to a false idea of its propriety. But the cause of good morals demands that the subject be given attention.

I suppose it will be conceded that immorality between the sexes is on the increase, that houses of assignation are often as well known as drug-stores, and that public places are full of women, who by their manners entice and furtively convey to men the idea that they share none of the fears of the modern wife concerning conception. The vice pervades our civilization. Mr. Hale, in his little book on social life in England, says that it is the rule there that young men must first settle with the mistress before they may venture to marry. Recent writers say that one birth in five in Scotch cities is out of wedlock, and in Paris one in three. In German cities it is little if any better. It may be said to be worse in our own country, in kind if not in degree, if we consider the indications of the wide-spread practice of abortion. If the whole subject were not considered so exceedingly sacred that it cannot even be mentioned, there would be some chance for young people to learn the debasing evils of prostitution and incontinence; wives might be more indeed the companions of their husbands; fewer home circles would be rent, and men generally would be freer from the temptation to go outside to satisfy nature's demands.

An eminent physician in this city, who is well known as one who treats nervous affections, a few years ago had under his care as a patient a delicate young woman who was engaged to be married. Her friends consulted him as to the propriety of her marrying, considering the state of her health. He advised that she should marry, *but that she should have no children for several years* at least, or until firm health should be established; and at the same time suggested that her affianced be referred to him for instructions. These instructions to the man were simply that he should in each instance withdraw in time to make the intercourse incomplete. The subsequent history is, that there was no child for three years; the wife became a hearty woman, stout and robust; but the man's health was so undermined that he seems to be permanently a victim to nervous affections of various kinds, and it is a question whether or not he is impotent. Though he was strong and robust at the time of marriage, he is now a delicate man. Naturally such a man is overweighted, and his mind is worried about himself, and it is scarcely to be wondered at that he lacks energy to pursue his business in successful competition with others. To my mind the physician made a grave mistake in his advice—at least so far as the man is concerned. Is it possible that the laity may look for no better advice on this subject from their medical advisers than such as I have just mentioned?

Your truly,

X. Y. Z.

Philadelphia,
October 25, 1888.

NOTES AND COMMENTS.

A Leech in the Larynx.

In the number of the *Centralblatt für Chirurgie* for May 26, 1888, there is reproduced the story of a French physician named Godet, who performed thyroidotomy upon a patient into whose larynx a leech had entered, and fastened itself below the glottis. In reading of the attempts to remove the animal, it seems singular that, before resorting to a cutting operation, an attempt was not made to overcome the animal with the vapor of chloroform. This agent has a very prompt effect upon many of the lower animals, and it seems possible that, if chloroform had been administered to the patient with her face turned downward and at a lower level than that of her body, the leech would have been narcotized and dislodged, without danger of its falling down into the trachea.

Uselessness of Günzburg's Test.

M. Constantin Paul (*La France Médicale*, Feb. 23) reports that this test for free hydrochloric acid in the gastric juice is unreliable. A small amount of sulphureted hydrogen, such as might exist in a somewhat stale egg, or an alkaline solution of phosphate of soda, as well as hydrochloric acid, gives a rose or red color with the test.—*N. Y. Med. Abstract*, August, 1888.

Creoline, Iodoform Ointment and Antipyrine in Eye-Practice.

In the *Centralblatt für Augenheilkunde*, September, 1888, Dr. Mergl states that creoline has been employed, in one per cent. solution, in acute and chronic conjunctivitis, in trachoma, and in ulcers of the cornea. In acute catarrhal conjunctivitis, the conjunctiva of the lower lid was brushed with a one per cent. solution twice a day; in most cases the redness and swelling of the conjunctiva disappeared in one or two days, the secretion lessened, but did not entirely disappear. He therefore thinks it better, after two or three days, to change the creoline solution for one per cent. nitrate of silver or sulphate of zinc. In chronic conjunctivitis creoline gave no favorable results. In four cases of trachoma the creoline appeared to act as a true specific—the redness and swelling disappeared in from two to four days, the purulent discharge in a week, and the granulations in from two to three weeks. In other cases the redness and swelling disappeared, but the granulations would not yield; in some cases the disease was aggravated. Mergl now begins the treatment of acute trachoma with creoline; if improvement does not progress rapidly, he changes it for nitrate of silver and copper. In trachoma combined with pannus or corneal ulcers, creoline is an excellent remedy; under its influence the ulcers become clean, the pannus recedes, and in conjunction with the use of atropine the ulcers are healed.

Although creoline very often brings about a cure of corneal ulcers, it also frequently fails. On the other hand, the ten per cent. iodoform-vaseline ointment employed by Dr. Kanka, is an invaluable remedy in ulcers of the cornea, especially in hypopyon. Upon the closed eye a piece of gauze spread with iodoform ointment is laid, and fastened with a bandage. Under the use of this bandage the pain diminishes, the ulcers become clean, and the hypopyon disappears in two or three days. Of fifty cases of keratitis with hypopyon under Dr. Kanka's care during two years, in only two was the pus evacuated by paracentesis. On the advice of Dr. Adolph Aldor, antipyrine was employed to clear up cicatrices on the cornea. As it caused burning, cocaine was first instilled into the eye and then the cornea dusted with antipyrine in the form of powder. After the flow of tears ceased, which occurred in a few minutes, massage of the cornea was practised. The result obtained was good. In the case of a child which, after an attack of small-pox, was affected with opacity of both corneæ, the procedure just described was employed; after three months the child's vision had increased from inability to see anything, to ability to walk alone and to recognize small objects, such as a watch and half-penny. The result was similarly favorable in two other cases.—*Wiener med. Presse*, November 7, 1888.

Transference of Syphilis by Means of a Razor-Cut.

Cheminade, Interne of the Hôpital Saint-Jean, Bordeaux, communicates a case to the *Annales de derm. et de syphil.*, No. 8–9, in which syphilis seems to have been transferred to a man by means of a razor. It seems that an officer, thirty years old, was cut with a razor in the right supra-hyoid region immediately below the angle of the jaw. The wound would not heal for a long time. Under the influence of different caustics a whitish crust was formed, which fell off and left behind an oval ulcer with indurated edges. At the same time the neighboring lymph glands became swollen. After about two months the ulcer healed, leaving a scar about one-third of an inch long. After three months mucous patches occurred on the cheeks, the arches of the palate and on both sides of the frænum of the tongue. The voice was hoarse, and there developed inflammatory œdema of the parts lying above the glottis. The lower lip was covered with syphilitic erosions.—*Wiener med. Presse*, Oct. 7, 1888.

Reduction of Subcoracoid Dislocation.

Dr. J. W. Marsee says in the *Indiana Medical Journal*, September, 1888:

"While in New York City recently I saw Dr. Bull reduce a subcoracoid dislocation of several weeks' standing, in a very simple and easy manner. The name of the inventor has escaped my memory. I have since practiced the method with very gratifying results in one case, in which the bone had been out for five weeks. After making free motions for a minute, to break up adhesions, he placed the elbow, bent to a right angle, against the patient's side, and holding it there carried the hand out, rotating the humerus until the forearm was horizontal; then holding the forearm so, carried the elbow toward the umbilicus. One effort sufficed to make the reduction; in mine two efforts were required. No force was used or needed."

Formulæ for Terpine.

M. Houdart in a recent thesis gives a good summary of the applications of terpine in therapeutics. The following are the principal formulæ (*Bulletin Médical*, August 22, 1888):

Terpine	gr. cl
Glycerine	f℥ ii

Dissolve with the aid of heat.

A coffeespoonful of this solution contains fifteen grains of terpine. It is administered in a mixture with sweetened water or syrup. The addition of alcohol makes a more complete solution. Each coffeespoonful of the following formula contains seven and a half grains of terpine:

Terpine	gr. lxxv
Alcohol (90°)	f℥ v
Glycerine (30°)	f℥ x

Dissolve the terpine with the aid of heat in the glycerine, add the alcohol, and keep in an hermetically sealed bottle. M. Houdart advises with M. Lépine to prescribe terpine as an expectorant in bronchitis in doses of seven and a half to fifteen grains, and in smaller doses in affections of the urinary passages. Increase of the dose should be avoided in patients with Bright's disease or other renal disease.

Photographing the Eye.

Although many have made repeated attempts to reproduce the appearances of disease in the eye by photography, the results have not been very encouraging. The difficulties have been so great that it has been impossible up to the present to photograph truthfully even the iris and the pupil. The chief of these difficulties has been perhaps the insufficient illumination, and it is in this respect that the magnesium flash light, so lately introduced, has proved its efficacy.

Cohn has made experiments with this light with most encouraging results (*Centralblatt für prakt. Augenheilkunde*, March, 1888). He has been able to photograph satisfactorily a pupillary membrane, a coloboma of the iris, and even the painted optic nerve of an artificial eye, as seen by the indirect method with the ophthalmoscope; and his conclusions are that, with an apparatus of sufficient precision, the possibility of photographing the living optic nerve does not admit of a doubt. His method is to mix equal parts of magnesium and finely powdered chlorate of potash with the dry finger on a piece of paper, and for each exposure to use about as much powder as can be taken between finger and thumb. He puts this on a little tin dish, having a diameter of about 15 mm. (¼ inch) and sides about 5 mm. ($\frac{1}{12}$ inch) high, and lights it with a small piece of punk stuck in the end of a stick somewhat less than a foot long. This small quantity gives quite enough light at a distance of 20–30 inches for all eye portraits, and causes neither troublesome smoke nor glare. It is so quick that the pupil does not contract till after the flash, and thus the natural size of the pupil in the dark is obtained. This is found to be very large, appearing almost as though a mydriatic had been used.

Certainly this method is a great advance, and, with the improvement which will be made in the technique, we may hope to have in this a simple and reliable means of representing diseased conditions of the anterior part of the eye—perhaps even of the fundus.—*Brooklyn Med. Journal*, July, 1888.

Albuminuria in Diabetes Mellitus.

Dr. Henry C. Coe, of New York, concludes a paper on this subject (*N. Y. Medical Journal*, July 28, 1888) with the following propositions:

"1. Albuminuria occurring in diabetes has the same import as in ordinary cases.

"2. A trace of albumin, appearing transiently or intermittently (when proved by exclusion to be of renal origin), and seldom or never associated with casts, may be regarded as due to irritation of the kidneys from the glycosuria. The immediate prognosis is good; but renal changes may subsequently result.

"3. The occurrence of persistent albuminuria and numerous casts in a case of diabetes of long standing is of grave import, as pointing to the existence of chronic nephritis; if acetone and diacetic acid are also present, the patient may die in coma at any time.

"4. Examination of the urine furnishes complete evidence of the patient's danger, even when the general condition is not such as to excite apprehension."

Sulphonal in the Night Sweats of Phthisis.

Dr. A. Martin recommends sulphonal in the night sweats of phthisis. He gives it in doses of seven and one-half grains taken before going to bed. He says it has proved very helpful, securing a quiet natural sleep lasting from four to six hours.—*Wiener med. Presse*, July 22, 1888.

Population and "The Struggle for Existence."

S. H. Mead (*Popular Science Monthly*, October, 1888) says: In Professor Huxley's article, "The Struggle for Existence," he states the obvious fact that, "so long as the natural man increases and multiplies without restraint, so long will peace and industry necessitate a struggle for existence as sharp as any that ever went on under the *régime* of war." But this promptly suggests the important modification that all classes of men do not increase equally. *Punch's* humorous statistics, a quarter of a century ago, gave to the well-to-do quarters of the town an average of only half a baby to each house. More serious observation shows, from the yeast-plant up, a steady diminishing rate of increase, pyramid-like, until the cap-stone is reached—an average human family consisting of five persons, the three children replacing the parents, with only one to spare. But the cap-stone itself diminishes to a point. The human race differs in fecundity—the worst nourished and most emotional being the most prolific, and the best fed and the best poised intellectually producing not enough to maintain their own numbers. The Dutch numbered about two millions. They created their country largely out of the ocean and survived a mud avalanche of cruelty and brute force. In South Africa, Java, New York, and elsewhere, they have been a permanent force, as well as in science, literature, arts, and arms. But their numbers have not greatly increased. On the other hand, the natives of the south of Ireland have been decimated by famines and chronic insufficiency of food. They have founded no distinctly Irish colonies anywhere, but contented themselves with adhering closely to Anglo-Saxon communities in all parts of the world, which contact they declare to be injurious to them. It is asserted that their numbers have increased in recent times from about six millions to thirty millions, more or less. Eminent men, like George Washington, leave few if any descendants. Napoleon, as the fruit of two marriages, had one child. Hardly any of the peerages in the House of Lords, consisting of some four hundred members, are more than two hundred years old, and if, as proposed, no new peerages should be created, the hereditary legislators would become extinct—the object aimed at by the proposal. The present tendency of civilization referred to by Huxley, to sacrifice the best to the worst perpetually, would seem at first sight to reduce the whole to a dead level of the worst possible. But further reflection shows the effect to be to raise the whole mass from the bottom. If the mass can be well fed, refined, and intelligent, nature will no longer throw off such frightful numbers of rudimentary men, but will be as niggardly of human beings as she now is chary of perpetuating great intelligences. In this direction there is hope that the problem may be solved.

Condensed Milk in Infant Feeding.

Dr. Charles W. Drew concludes an article on condensed milk in infant feeding in the *Northwestern Lancet*, September 15, 1888, with the following words:

"The question therefore presents itself to the conservative physician and to the mother and nurse, whether there is in any ordinary case sufficient advantage in the use of condensed milk as an infant food, to warrant them in assuming the risk of continuously administering as a substitute for mother's milk a mixture containing thirteen per cent. of its weight of such an undesirable and possibly deleterious constituent as cane sugar, as they must do if the condensed milk is simply diluted to the point of furnishing the proper percentage of fat, casein and salts which experience has proved to be necessary for the growth and development of the child. It is impossible for a single logical argument to be adduced in support of such a proceeding, and it must be concluded that from all the evidence attainable by a full study of the chemistry of the subject, that the use of condensed milk in infant feeding is unwarranted, and should be disapproved and discouraged by all conservative physicians."

Hunyadi Janos Water.

Dr. Dieterich, in the *Pharmaceutische Centralhalle*, gives the following formula for making the artificial water:

Potassium sulphate	0.5 parts
Sodium chloride	14.0 "
" bicarbonate	52.0 "
" sulphate, dry	180.0 "
Calcium sulphate, precip.	15.0 "
Magnesium sulphate, dry	24.5 "
Iron sulphate, dry	0.2 "

Taken in grammes the above will produce 10 liters (10½ quarts) of the artificial water.

Dose, put a tablespoonful of the salt into a half-pint bottle, fill it half full of water, dissolve by shaking, then fill with carbonic acid water.—*Pharmaceutical Era*, October, 1888.

Medicated Biscuits.

This form of medication, says the *Chemist and Druggist*, Sept. 22, 1888, is often used on the Continent, especially for children. The usual way is to give to a pastry-baker the medicines in the shape of powder, to be mixed with the biscuit-paste and divided into a given number of cakes. As an accurate division is thus seldom secured, M. A. Xanthopoulos, of Makri-Keni, Turkey, has proposed the following process, to be executed by the pharmacist himself. Take the medicine prescribed, mix it with four times its weight of powdered sugar, and divide into the requisite number of doses. Now spread each powder with a brush on the spongy side of a well-baked biscuit, and apply over it a coat of thin mucilage. After drying in a warm place, the cakes may be dispensed. To give a better finish, a little powdered starch and sugar may be dusted over the medicated side before the mucilage is quite dry. M. Xanthopoulos recommends the process as a quick and convenient one, affording all the accuracy necessary in the exhibition of medicines.

Psychic Effects of Hasheesh.

Mr. A. M. Fielde has recently recounted his experiences under the influence of hasheesh. He smoked the hasheesh until he felt a profound sense of well-being, and then put the pipe aside. After a few minutes he seemed to become two persons: he was conscious of his real self reclining on a lounge, and of why he was there; his double was in a vast building made of gold and marbles, splendidly brilliant, and beautiful beyond all description. He felt an extreme gratification, and believed himself in heaven. This double personality suddenly vanished, but reappeared in a few minutes. His real self was undergoing rhythmical spasms throughout his body: the double was a marvelous instrument, producing sounds of exquisite sweetness and perfect rhythm. Then sleep ensued, and all ended. Upon another occasion, sleep and waking came and went so rapidly that they seemed to be confused. His double seemed to be a sea, bright, and tossing as the wind blew; then a continent. Again he smoked a double dose, and sat at his table, pencil in hand, to record the effects. This time he lost all conception of time. He arose to open a door: this seemed to take a million years. He went to pacify an angry dog, and endless ages seemed to have gone on his return. Conceptions of space retained their normal character. He felt an unusual fulness of mental impressions—enough to fill volumes. He understood clairvoyance, hypnotism, and all else. He was not one man or two, but several men living at the same time in different places, with different occupations. He could not write one word without hurrying to the next, his thoughts flowing with enormous rapidity. The few words he did write meant nothing. This experience admirably illustrates the close relationship between states of real insanity and transitory affections induced by psychic poisons.—*Science*, Oct. 12, 1888.

Cremation of Filth at Montreal.

The Albany Board of Health is considering the use of crematories for garbage and night soil, and the Health Officer, Dr. Balch, recently made an inspection of those at Montreal which he describes as follows:

These crematories are worked under a patent owned by William Mann, of Montreal, and consist of two different plants. The one for garbage is situated in a thinly-settled part of the city, and consists of a brick furnace into which the garbage is received from an upper floor, while the fire-box is on the floor below at one end of the furnace. The garbage falls from the upper floor to grates within the furnace, and the fire is allowed to pass over, evaporating the moisture, which allows of the garbage itself igniting as soon as it becomes perfectly dry; the ashes resulting (from the combustion) fall through the grate bars, where they are removed to be used as filling. The chimney at the opposite end of the fire-box is about eighty feet high. No perceptible smell was present, and no complaint from the neighborhood had been received that the smoke caused any nuisance. The crematory for night soil consisted of two furnaces upon a single chimney, and was in the main similar to the one for garbage, except that no grate bars were placed within the furnace, the night soil being allowed to rest upon a raised floor over which the fire passed in the same manner as already described. The probable cost of erection for a furnace sufficient to destroy the garbage in Albany, including the cost of the patent, would be about from $4,000 to $5,000. The fuel used is the cheapest kind of soft coal and coal screenings, and the amount needed about two tons a day. It will require, he says, three or four men to do the necessary work at the plant.—*Engineering and Building Record*, October 20, 1888.

Treatment of Malarial Cachexia.

Dr. J. J. Mulheron says that in the cachexia which ensues on the prolonged action of the malarial poison the ferruginous tonics and the medicines known as alteratives, are indicated. The following, which he says might be known as the tincture of the five chlorides, is an excellent combination for this condition, as it is in poverty and depravity of the blood from any cause.

℞ Hydrarg. chlor. corrosivi . . gr. ii
Tr. ferri chloridi,
Acidi hydrochlorici dil. . . āā ℥ iii
Liquoris acidi arseniosi . . . ℥ iss
Potassii chloridi . . . . . ʒ ss
Syrupum simplicem . . q. s. ad ℥ vi

M. Sig. A teaspoonful in water four times a day.

He calls attention to the fact that it is the chloride and not the chlorate of potassium which is called for in this prescription. He thinks the average druggist will require to have his attention especially directed to this fact. The chloride of potassium, he says, is a peculiarly valuable salt in the treatment of anæmia. The necessary regulation of diet, hygienic precautions, etc., must, of course, receive attention.—*Medical Age*, Sept. 25, 1888.

Formula for Gastralgia and Vomiting.

Ewald, says the *Wiener med. Presse*, September 23, 1888, advises the following formula in hysterical hyperæsthesia, gastralgia and vomiting:

℞ Morph. muriat. . . . . gr. iii
Cocaini muriat. . . . . gr. ivss–viiss
Tinct. belladonnæ . . . . . ♏ lxxv–cl
Aquæ amygdalæ amar. . . . . ℥ vii

M. Sig. Ten or fifteen drops to be taken hourly.

Cannabis in Graves' Disease.

Rafaele Valieri, of Naples, has successfully employed cannabis in three cases of Graves' disease, after all other means had been tried without effect. The following are the formulæ he employed:

℞ Cannabis . . . . . gr. ivss
Sacch lactis q. s. ut fiant pil. No. V.
Sig. To be taken in 24 hours.

℞ Cannabis . . . . . gr. ivss
Aquæ destill. . . . . ℥ iii
Syr. flor. aurant. . . . . ℥ viiss

M. Sig. To be taken in tablespoonful doses in 24 hours.

—*Wiener med. Presse*, October 7, 1888.

Cincinnati Polyclinic.

The Cincinnati Polyclinic was organized October 31. Dr. Charles A. L. Reed was elected Dean of the Faculty; Dr. Longstreet Taylor, Secretary; Dr. Rufus B. Hall, Treasurer. The Faculty consists of: Drs. A. C. Kemper and E. W. Mitchell, in Internal Medicine; Dr. H. W. Rover, in Pædiatrics; Drs. Edwin Ricketts, Rufus B. Hall, and Charles A. L. Reed in Gynæcology; Drs. A. B. Thrasher and J. H. Boylan in Laryngology; Drs. A. Ravogli and M. Ricketts in Dermatology; Dr. Robert Sattler in Ophthalmology; Dr. Longstreet Taylor and Wallace Neff in Surgery, including Genito-Urinary Diseases.

Almost the entire Faculty are teachers in one or the other of the three Medical Schools of Cincinnati, and the majority of them hold important hospital appointments. A large clinic has already been developed.

NEWS.

—An International Congress for Criminal Anthropology will be held in Paris, August 4–8, 1889, under the honorary presidency of Prof. Brouardel.

—The *Medical Standard*, Nov., 1888, states that there are 80 patients with typhoid fever in the Chicago County Hospital, in a total of 486 inmates.

—There were 28 new cases and 3 deaths from yellow fever at Jacksonville, Fla., Friday, November 2. Eight cases have been reported at New Decatur, Alabama.

—A strange accident happened to a man in Asheville, S. C. He was trying to pull off a tight-fitting boot while sitting in a chair, when his right femur was broken by the strain.

Dr. George H. F. Nuttall, of San Francisco, has been awarded the Boylston prize of four hundred and fifty dollars for his essay entitled: "A Contribution to the Study of Immunity."

—Dr. McCully, of Toronto, discharged a revolver into a crowd of medical students who had gathered in front of his house and were behaving in a riotous manner. One student was shot in the leg.

—The *St. Louis Med. and Surg. Journal*, Nov., 1888, says that in Turkey, by decree of the Sultan, as soon as a physician dies his diploma must be turned over to the authorities, who return it to the college from which it was originally received.

—We learn from the New York *Medical Record*, November 3, 1888, that the hospital Saturday and Sunday collections in that city last year amounted to $50,449.15. Of this amount $28,626.79 was from religious sources and $21,822.36 from secular sources.

—Dr. Frank L. Wyman, of Olneyville, Rhode Island, has been awarded $17,000 damages from the Union Horse Railroad Company for injuries received by being hurled from the front platform of a car, which was driven at great speed in rounding a curve.

—During six months of high license, the number of saloons in Paterson, N. J., is said to have been decreased by 125, and the receipts from licenses increased by $40,000. It is estimated that the taxpayers will be relieved of taxes to the amount of $100,000 a year from the increased revenue from licenses.

—The Council of Public Hygiene for the department of the Seine, Paris, at its meeting October 13, appointed a committee to obtain information concerning the value of vapor of turpentine as a prophylactic against the necrosis from phosphorus which occurs among workers in zinc. MM. Trost, Lancereaux, Trélat, Brouardel, Riche and Poligot are on the committee.

—The *New York Medical Journal*, Nov. 3, 1888, expresses the opinion that the chewing of gum may be advantageous under certain circumstances, inasmuch as it increases the secretion of saliva, and thus may, if used at the proper time, materially assist the digestion of amylaceous food. It also serves to cleanse the teeth, and may exert a wholesome influence upon the pharynx in catarrhal conditions.

—In commenting upon a suit for damages brought against a physician by the parents of a child which died after taking a mixture containing antipyrine and sweet spirits of nitre, which was prescribed by the physician, the *National Druggist*, November, 1888, declares that the crystalline deposit (isonitroso-antipyrine) produced by the union of these two agents is not poisonous. The Editor says he has tested its toxicity upon himself, as well as upon the lower animals.

PEOPLE WHO ARE NOT FAMOUS can become so and have their pictures put in the papers by signing a medicine paper and certifying they have been cured of a terrible disease they never had.

HUMOR.

AS DELICATE a charity as I remember was the act of a gruff, taciturn old physician in a Colorado mining town. A poor, aged parson was carefully attended by the irritable doctor. When the preacher had sufficiently recovered to dispense with further medical attention he asked for his bill. "Your bill? Here it is," said the doctor, opening his pocket-book and handing the minister's wife a $10 bill.—*America* (*Chicago*).

CUSTOMER—"That was splendid insect powder you sold me the other day, Mr. Oilman." Mr. Oilman (with justifiable pride)—"Yes, I think it's pretty good—the best in the trade." Customer—"I'll take another couple of pounds of it, please." Mr. Oilman—"Two pounds?" Customer—"Yes, please. I gave the quarter of a pound that I bought before to a black beetle, and it made him so ill that I think if I keep up the treatment for about a week I may manage to kill him."

WOULDN'T DRINK ANY.—Old Jefferson Catnip, upon his first visit to the city, went with a friend to a restaurant. While they were sitting at a table a young fellow, carrying a lawn tennis racquet, came into the room. Old Jefferson, after regarding the instrument for a few minutes, turned to his friend and said: "John, I drink no milk in this town." "Why not?" "Why not? Jest look at the strainers they use. Why, you could shove a catbird through 'em."—*Arkansas Traveler.*

DIED.

Clara Lucile Sundberg, *née* Blackman, wife of Dr. John C. Sundberg of San Francisco, California, October 21, 1888.

OBITUARY.

R. LEONARD, M.D.

Dr. R. Leonard, of Mauch Chunk, a prominent physician of Carbon County and President of the Lehigh Valley Medical Association in 1884, was killed by a passing train while walking home from a visit to a patient, shortly after midnight on the morning of October 26. Dr. Leonard was graduated from the Vermont Academy of Medicine in 1845. He was a member of the Carbon County Medical Association, and one of the surgeons to St. Luke's Hospital, Bethlehem, and was 65 years of age at the time of his death.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SOLUTION FERROUS MALATE.

(Amer Phar. M'f'g Co.) 4 Grs. to Fluid Drachm.

DOSE —30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat, and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

Solution-Salicylate of Iron

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful four times a day.

An unfailing remedy in acute or chronic Rheumatism, where deformity has not yet resulted. Has also been prescribed with great satisfaction in other affections where Salicylic Acid. Bi-carb. Sodium and Ferrous Malate are indicated.

Ferrous Malate, Gentian & Cinchona

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

COLLEGE HILL, OHIO.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

Clinical Lecture.

FISTULA IN ANO; LARGE SEBACEOUS CYST OF THE SCALP; LIGATURE OF THE FEMORAL ARTERY FOR ANEURISM; AMPUTATION—USE OF RELAXATION SUTURES.[1]

BY JOHN H. PACKARD, M.D.,
SURGEON TO THE PENNSYLVANIA HOSPITAL.

(Reported by William H. Morrison, M.D.)

Fistula in Ano.

Gentlemen: The first patient I shall bring before you to-day has an anal fistula, sometimes called a fistula in ano. A false passage exists, opening by one end within the bowel, by the other on the surface of the skin near the anus. The history of this case is obscure, but probably the lodgment in one of the rectal pouches of some insoluble matter, such as a seed, for instance, has given rise to abscess, the breaking of which externally has established an abnormal channel or sinus. Sometimes very little pain results from such a condition; but this man suffers greatly, and desires relief. The radical way of affording this is to divide the bridge of tissue which overlies the sinus, and make the gap heal up from the bottom.

Not very long ago it was thought necessary always to dissect out the wall of the fistulous passage; and this is still the popular idea of the operation. Such a procedure is required in some cases in which the callous tissues bordering the sinus, which has been of long standing, would be very slow in healing. An instance of this kind occurred to me recently; the anus was nearly surrounded by a canal with very firm, almost cartilaginous walls. Under antiseptic precautions, I dissected all these away with a knife and curette, suturing the margins of the extensive wound thus produced, and then applying an antiseptic dressing.

In the present case, I pass a grooved director through the fistulous opening, and bring its point out at the anus. In order to do this, I put my other index finger into the rectum, to guide the tip of the instrument; not finding the inner orifice of the fistula, I push the end of the director through the thin wall, and now bring it out easily. I now pass a curved bistoury along the groove, and divide everything until the director is completely freed, cutting through nearly the whole thickness of the external sphincter muscle. Now (and this is a very important point) I explore the wound carefully with my finger to make sure that there are no sinuses extending in other directions. Finding none, the operation is completed by packing the wound with lint and iodoform ointment, and applying a T-bandage.

Large Sebaceous Cyst of Scalp.

This man has, as you see, a tumor about as large as an egg on the side of his head. It is what is generally called a wen, and is nothing more than a retention-cyst developed from one of the sebaceous follicles of the skin. Such tumors are often met with in this region, the scalp containing a great many sebaceous follicles. Sometimes they

[1] Delivered at the Pennsylvania Hospital.

attain a very much larger size than the one now before you.

Growths of this kind are quite harmless, but are inconvenient and unsightly. Occasionally they inflame and suppurate, and then there is danger of absorption of the products of inflammation, causing blood-poisoning. The density of the skin renders the divided veins liable to gape, and pus or even putrescent materials may be carried into the circulation. Erysipelatous inflammation, extending to the membranes of the brain, and sometimes involving the brain-substance itself, was formerly a not infrequent result of operative interference in these cases. With our present methods the danger of this sequel is set aside.

This man's scalp has been carefully shaved and rendered aseptic in the way familiar to you; and I will now divide the skin over the tumor, turn the flaps aside, and dissect out the cyst entire. There is not any bleeding of consequence. As the skin is somewhat redundant, a portion of it is clipped away; not too much, lest there should be tension upon the edges. Catgut, for drainage, is now laid in the wound; the edges are brought together and sutured with catgut; protective, iodoform, sublimate cotton and a bandage complete the dressing.

Ligation of the Superficial Femoral Artery for Aneurism.

This patient has an aneurism of the left femoral artery just below Hunter's canal; that is, just as the vessel emerges from the mass of the great adductor muscle. He does not know to what to attribute the aneurism, but has been aware that something was wrong with the part for some eight or nine months. He denies that he has ever had syphilis, or any other form of venereal disease; and while in very many cases the occurrence of aneurism is the result of degeneration of the arterial walls by syphilitic change, its existence is not at all to be assumed as proof of such change. In the present instance we may accept the patient's statement, and suppose that under some excessive strain the walls of this vessel yielded.

I shall not take up your time with a discussion of the various forms of aneurism, which will be described to you elsewhere. We have before us a dilatation of the artery, forming a tumor perhaps as large as a walnut, pulsating strongly, and giving the impression that its wall is thin. Left to itself, the wall would become more and more thinned, until it would give way, and there would be a diffuse hemorrhage into the tissues of the limb. If the rupture should take place through the skin, enough blood would soon be lost to deprive the patient of life. To prevent either of these accidents, I am going to stop the flow of blood through the distended portion of the vessel, which will become full of clot; this will organize into a solid mass, and the nutrition of the parts supplied by this vessel will be carried on by the blood flowing through the branches of the profunda. There are various ways of effecting this closure, but the one I shall adopt in this case is the tying of the trunk of the vessel where it is healthy, above its entrance into Hunter's canal.

Standing on the outer side, I begin at a point seven inches below Poupart's ligament, and carry an incision upward for three inches along the inner edge of the sartorius muscle. Drawing this muscle outward, I work down with my fingers and knife-handle, and come almost immediately upon the vessel, beating under my fingers. A small nick made in the sheath enables me to pass a grooved director under the vessel from within outward; the director is curved, with the groove in the concavity, and along the groove I carry a short, blunt, curved needle armed with the ligature, which is thus placed in position. The two ends of the ligature are now lightly closed in a single knot, when the pulsation in the tumor is found to be arrested. The knot is therefore drawn tight, and another one made, securing the vessel. Both ends of the ligature, which is of thick catgut, are cut off short; the wound is closed with sutures, catgut for drainage being first laid in it, and antiseptic dressings are applied. The limb will be, for a few days, wrapped in cotton; and the patient will be kept at absolute rest.

There are very few surgical procedures in which an accurate practical knowledge of anatomy is more essential than in the ligation of arteries. The object of the operator must be to expose the artery and apply the ligature with the least possible disturbance of the tissues. He must know where the artery is to be sought, and what its relations are to the vein or veins and nerves which accompany it. I think I have seen more difficulty encountered in the tying of the subclavian artery than in any other simple surgical operation. On one occasion I saw an experienced operator about to tighten his ligature about one of the heads of the median nerve, when a bystander asked him if he was sure it was the vessel, and fortunately the error was corrected.

Amputation—Use of Relaxation Sutures.

The case which I next bring before you is one which you saw two weeks ago. You will remember that the man had fractured his left femur on two occasions within a period of eight months. At that time I told you that I should amputate the thigh at the next clinic. Two days after you saw him, it was found that he had had some hemorrhage. I therefore decided to call a consultation as the danger of further bleeding was imminent. It was then determined that the operation should at once be performed. Since the amputation the patient has done well. You see that the appearance of the wound is satisfactory. I call your attention to the fact that we used a relaxation suture placed three inches from the edge of the upper flap and one and three-fourths inches from the edge of the lower flap. The mark which it produced can still be seen. This mark is evidence that the relaxation suture was needed and that it held the flaps together. The use of relaxation sutures in amputation wounds brings the deeper parts together and facilitates their union. It also prevents the accumulation of serum and of the products of inflammation, and obviates the risk of tension upon the superficial sutures uniting the edges.

HYSTERICAL DYSPHONIA; EMPYEMA; THE GOUTY DIATHESIS.

BY BEVERLEY ROBINSON, M.D.,

CLINICAL PROFESSOR OF MEDICINE, BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

Hysterical Dysphonia.

Gentlemen: I saw this young woman for the first time yesterday. She tried to tell me her history, but I was unable to understand her, and a friend who accompanied her had to explain what she wished to say. When asked what is the matter, she tries to speak, but it is in a very low whisper which can scarcely be understood. She spoke a little better yesterday, and also this morning. She has had loss of voice about two weeks. During that time she has had no cough, no cold, no pain in the chest, no fever. Last winter she was "hoarse" in a similar way for ten weeks, the difficulty commencing suddenly and disappearing suddenly. It is supposed that it then began with a little cold. It is extremely rare during acute inflammation of the laryngeal mucous membrane to have as complete loss of voice as this patient has. If such loss of voice occurred during an acute laryngitis there would probably be more or less cough, fever, difficulty of breathing, some noise in inspiration and expiration, and oppression over the chest. Occasionally loss of voice follows a cold, and the symptoms just mentioned are absent; but this is rare. The condition of this patient may be only nervous, that is to say, hysterical; but what that is, we do not know. On asking her whether she has a lump in the throat, or a pain in the top of the head, she says she has not; her monthly periods are normal. These facts do not point toward hysteria. She says she laughs and cries readily, but she laughs only when things please her, and cries only when injured or displeased. Some hysterical women, you know, laugh when hurt, and cry when pleased. On inquiring whether she had any great fright or strong emotion when she lost her voice, she replies that it occurred when she experienced a great pleasure. Thus it would seem that her difficulty with speech is at least partly emotional.

Incidentally I might mention the case of a young woman who had lost her voice completely for ten months. During that time she had been given cough mixtures and a variety of remedies, but her voice did not return. Recognizing her trouble as nervous, I treated her for a short period and succeeded in completely restoring her voice; she has not failed for five or six years to express her thanks annually for the service I rendered. Before I became a general practitioner I saw a good many distinguished singers for throat difficulties, and I will allude to one case in which a lawsuit had developed between the singer and her manager. The physician who had been called in had said that she was unable to sing because of congestion of the vocal cords; but he had not examined her larynx. He had only assumed that because she had lost her voice she had congestion of the cords As far as I can remember, there was no reason for supposing that there was congestion of the cords other than the loss of voice. I was called in as an expert, and on examination found the cords white, and showing no sign of congestion. Thus you will see that a positive diagnosis of congestion of the cords cannot be made without a laryngoscopic examination. I made such an examination yesterday in the patient before us, and found the cords white. But when she attempted to speak she could not bring the free margins of the cords directly

together. It would now seem that her inability to speak was due to the effect of joy; it might have been due to grief. If she had given a history of a cold existing a week or two before the occurrence of loss of voice, that might account for it. Some of the most obstinate cases of loss of voice which I have seen followed a cold, and were due to loss of power in the muscles of the larynx.

In the case before us I believe I can restore the voice at once; that I can make the patient talk by introducing this applicator into her larynx. [Dr. Robinson assured the patient she would be able to talk. On introducing the applicator down to the larynx and quickly withdrawing it, he commanded her to count: "one, two, three"; and after gentle but firm urging she repeated the numbers in a clear voice.]

I had a friend once who received a large fee by restoring the voice of a patient in this way. His success resulted only from a mental impression—the conviction being forced upon the mind of the patient that she could and would speak. Wishing to reserve this experiment for to-day, I had to give her something yesterday, and chose a stimulant for the vocal cords, consisting of:

Tinct. benzoin. comp.,
Ol. pini sylvestris,
Acidi carbol. liq.,
Tr. iodi comp. . . . . āā f℥ ii

M. Sig. Use half a teaspoonful to a pint and a half of hot water as an inhalation four or five minutes every two or three hours.

Of course the patient should not be allowed to go into the cold air for a while after the inhalation. The inhalations can be made by placing a newspaper cone over a pitcher containing the hot fluid. There is nothing better to allay irritation of the larynx than compound tincture of benzoin, and to this may be added the firwood oil; but there is no necessity for the carbolic acid or compound tincture of iodine. If the patient had had acute inflammation of the larynx I should have used compound tincture of benzoin alone.

What more should I do for this patient? Well, I learned from a woman the other day that a mixture of sweet oil and mustard makes slight irritation, and can be kept on the skin over-night without distress to the patient. I think I would try that in this case, placing the poultice on the neck over-night, which would act as a counter-irritant and help restore tone to the larynx, especially to the crico-thyroid muscle. I might have put on iodine, or a plaster, or a fly-blister, but I had mercy on the patient and tried the milder measure first. But repeating a fly-blister over the neck might have a very good effect in restoring the voice, if it could not be done in a milder way. Although the measures resorted to in her case did not restore the voice, yet the general practitioner is likely to go on with their use until he loses credit with his patient and her friends. There are a number of stimulating remedies which women know about, and one will declare her ability to restore the voice, for instance, by a mixture of lemon-juice and white of egg—which might succeed, and if it did not it would do no harm—or by a piece of borax in the mouth, or a piece of nitre. An ounce of the wine of coca, or the touch of a sponge-applicator, may also succeed. If the patient had been at my office I should probably have put an astringent on the applicator before introducing it, in order to increase the mental effect. You must influence the patient's mind, and a good way to do that is to apply electricity to the vocal cords. Place a necklet around the patient's neck with a brass plate over the tensor muscle, which is the seat of one pole, while the other is applied directly to the cord by the aid of a laryngeal mirror and a strong light. Test the strength of the current beforehand by touching it to your tongue. Apply it for a few seconds until the patient chokes, then take it out, and repeat the process several times. Give a sitting every other day for a week or longer, and the voice will return and continue to grow stronger until it becomes normal. If you can not do this, then use Faradism outside, employing a mild current. Benzoic acid lozenges are of use in these cases. They are preferably made up with black currant paste, a grain of benzoic acid in a lozenge. One may be taken every hour or two.

The differential diagnosis will suggest itself to each of you. You might search for an aneurism, or for diphtheritic paralysis, or acute laryngitis. But nothing will be of greater aid to you in these cases, and indeed in the general practice of medicine, than the ability to make a laryngoscopical examination. Such examination will often be of service, and inspire your patient with confidence. In cities, it is true, there are such minute divisions of specialties that one is not expected to use all the measures of diagnosis and treatment which might be of much advantage in practice in smaller places, where it is less convenient to send patients to specialists.

Empyema.

Dr. J. B. Kennedy, of Long Island City, sent me this patient with the following note: "I first saw the patient on the 19th of last June. He had a temperature then of 104.5°, and a pulse of 120. There was pain in the right side. Three days later there were signs of fluid in the pleural cavity. I waited a day or two, then put in the hypodermic needle and drew off pus from the right pleural cavity. I then aspirated and drew off nine pints. The fluid reaccumulated, and within a week I drew off seven pints more." A few days later Dr. Kennedy made an opening into the pleural cavity and put in a drainage tube, which remained in position until a few days ago. Dr. Kennedy was good enough to send the patient to me to ask my opinion on two points: First, as to the propriety of reintroducing the drainage tube; second, if the patient will be likely to become phthisical.

The drainage tube fell out while the Doctor was dressing the wound. Is that a good indication or a bad one? I should call it a relatively good one, for it probably fell out because the pleural cavity was small—it was closing up, the tube did not pass in far, and consequently fell out. We want the pleural cavity to become closed by recession of the chest walls or expansion of the lungs, or both, and plastic adhesion of its walls. But I cannot say, until after an examination of the patient, whether or not that was the cause of the falling out of the tube. The patient says he has a good appetite, and that he has no cough; he is gaining flesh, there is no elevation of the temperature. The external opening, as you see, has closed. It was situated a little outside the right nipple—rather an unusual place for a spontaneous opening to occur. Dr. Kennedy might have seen pointing taking place there, and therefore have chosen it as the place to make his opening. Anyone can make the opening in a case of empyema, unless it is intended to take out a section of rib. Adults, as a rule, do not recover without an operation, with or without exsection of a rib.

On looking at his chest we find it is pretty well developed on the left side; the left lung should be well formed, for it has been doing more work than normal. On the right side, the walls of the chest are less retracted than would be expected from the history. I assume the reason of this is that the lung has expanded. How is that to be determined? By percussion; and yet per cussion will not help much, for there is a thick membrane covering the lung arising from the pleuritic exudation. I hear respiratory sounds all over the right side anteriorly and posteriorly, but there is greater dulness beneath the axilla. Nevertheless the lung is pretty well expanded, and the rational history is good. How can we tell whether or not there is any fluid in the right pleural cavity? No man can tell positively that there is none unless he aspirates. On introducing the needle of the hypodermic syringe I am unable to obtain any fluid We conclude then that the cavity has completely closed.

Now the practical question arises, Will this young man have phthisis? There is no sign of it at present. He is gaining weight; has no cough; the pleural walls are healing up; he has no inherited history of phthisis. But you ask, Why did he have empyema? There are a good many cases in which empyema develops as such from the very beginning, and not as a result of acute or subacute pleurisy; in other words, the acute or subacute pleurisy is an empyema from the onset. It may not be possible to account for it by the history, by the surroundings and accidental circumstances, yet empyema may develop from the start. This young man says he lives in a damp house on Long Island. I have told him that he is very likely to have phthisis sooner or later unless he guards against evil habits, such as drinking, especially of bad whiskey, sitting up late, smoking tobacco, etc. Whatever else he may do, he should move into a perfectly healthy locality, where there is no malarial poison, no sewer gas, but plenty of sunlight and pure air. If he will observe these instructions for a year, and manage to keep up good nutrition, I think he will escape phthisis. But if he exposes himself in the ways mentioned, or if he becomes overfatigued, or catches a cold, he will probably be attacked at a point where there is least resistance, and it will probably be in the pleural cavity. If he again develops trouble there it will be a suppuration, and will probably end in tuberculosis sooner or later.

If his appetite fails, he should be given tincture of cinchona; if he loses flesh, cod liver oil should be administered; if tubercle bacilli are found, I should use creasote internally and by inhalation. At present I have greater faith in creasote than in any other agent in phthisis, although of itself it will not cure the disease

The Gouty Diathesis.

This old man has gout and asthma. Seeing that other measures gave him little

relief, and learning that he had been troubled with gout, I determined to treat the latter, and gave him an alkaline mixture and colchicum; but it has apparently done him little good. He has some heart trouble, an old fibrous bronchitis, emphysema, old age, and conditions which cannot all be cured at once.

I have under my care a lawyer in comfortable circumstances, who lives a somewhat sedentary and intellectually laborious life. He had no family, and gout manifesting itself I sent him to Europe, where he spent the summer of 1888 under the care of a medical man, who told him he might return in the fall and that he would be able to pass the winter in New York without further trouble. The patient felt very cheerful after this counsel, but he had not been in New York long before he was seized with an attack of dyspnœa, which induced him to come to me. I examined him carefully all over, but could find nothing to account for the trouble. Having known him in the past, however, I was convinced that his trouble was gout. He had some dyspeptic symptoms which I treated, and with benefit for a day or two, so that he thought he was all right; but I had my doubts. Soon he returned with the same difficulty in breathing. I told him I believed the dyspnœa to be an expression of the gouty diathesis, and that he needed treatment for gout. I gave him colchicin, night and morning, and after three or four days he became better, and is now feeling quite well; but he is still eliminating oxalates and urates in excess. That man had no expression of gout other than the dyspnœa, yet the latter was certainly of gouty origin and would not improve without a recognition of the gouty diathesis.

My object in showing this aged patient to you is to call attention to the fact that the underlying cause of a symptom must be reached, otherwise treatment will be unsatisfactory.

—In order to avoid acrimonious and fruitless discussions, the Glasgow Pathological and Clinical Society requires that every communication made to it shall be accompanied by a specimen of some kind (if only a pathological product, a drawing, or a patient), so that, whatever opinions and theories may be raised with reference to the communication, the specimen can always be referred to and recorded as a fact.

COMMUNICATIONS.

ON SOME MILD MEASURES IN THE TREATMENT OF INTRA-NASAL HYPERTROPHIES AND INFLAMMATIONS.[1]

BY W. H. DALY, M.D.,
PITTSBURGH, PA.

In the early part of the present decade, when American laryngology was, in a figurative, general sense, in its first short clothes, the intra-nasal structures comprised a region upon which the profession—even those of us who were then freshly budding laryngologists—rarely ventured surgically without a misgiving that we were doing something that was unorthodox. These were the days when the war-cry had not yet been sounded by the pioneers on the out-posts to attack the enemy in the nose; that here some of the chief destroyers of mankind lay hidden; that in the interior of these curled, irregular, and mysteriously arranged chambers and their more adjacent cavities, the antra, frontal sinuses, and ethmoidal cells, lurked many of the sources of fleshly ills from the myxomatous polyp to the predisposing cause of hay asthma. In these days, you will remember, our armamentarium did not include so many of the instrumental devices for working in the nose as have since been given to us by the fertility of our collaborators; and, as my lot was cast in "out of the way" Pittsburgh, where instrument makers were not convenient, much of my work upon the interior structures of the nose was done with serrated edged scissors of my own pattern. And by the way, I am very fond of using the same instruments yet, whenever I can adapt them to the work in hand. I was upon one occasion, during these earlier times, consulted by a brawny iron-worker, who complained of compulsory mouth-breathing. Upon examination I found the difficulty was caused solely by a bagging hypertrophy of the soft tissues, over the inferior turbinates, anteriorly, in each nostril. The patient said that he had hunted for my office all over the city, and insisted on having something radical done at once.

In my disposition to oblige his importunate demands, I proposed that I should with the angular serrated scissors cut off the bagging hypertrophy in one nostril, then

[1] Read before the American Laryngological Association at its meeting in Washington, D. C., Sept., 1888.

plug the cavity with a styptic cotton plug upon a piece of rubber tubing, and asked him if he could stand a little cutting, to which he answered lustily: "Yes! I am no boy. I can stand to have my head cut off." Everything in readiness, I proceeded, when at the first crush of the scissor blades, and before they had met in the tissues, the patient yelled for me to stop, and laying hold of my hands, withdrew the scissors from his nose, and then fell to the floor, fainting. As he slowly recovered from this condition, by my elevating his feet, the blood began to flow in the most alarming manner from the wounded tissues, and in this state it was with difficulty I restrained him from running out of my office. He persistently refused to allow me even to look into the cavity again.

I am not sure whether the alarming hemorrhage finally ceased from my external compression on the alæ nasi, or the exhaustion of the patient, since he would not allow me to plug the nostril. He left as soon as he could get away, with an altered mind concerning radical measures and a faded courage, but a steady determination fully expressed to have nothing more to do with me.

I never saw him again until a year or more afterward, when he fell under my care as a heritage from my colleague who preceded me in service in the medical wards of the Western Pennsylvania Hospital.

The man was then a convalescent from another ailment, and I obtained a history of his case after the operation to which I have in the foregoing lines referred. He told me that he bled from the naris more or less for ten days after the cutting, when gradually good breathing-capacity supervened in that nostril and it continued in this free and open condition, even when he suffered otherwise with cold in the head An examination was now permitted by the patient, and I found the right naris, upon which I had made the frustrated attempt at abcision, to be in a normal condition, revealing no scar or other evidence that it had ever been other than normal. Its fellow was, however, in its old condition of stenosis

To me, there was a valuable lesson in this case, which I determined to turn to an account, and to this end I persuaded the man to allow me to use similar means, of a milder nature, in the other naris. This was at last consented to, and at intervals of a few days small and deep punctures were resorted to, with a knife similar to that used for incising the cornea in the extraction of cataract. I abstracted from one-half to three ounces of blood at a sitting; and in a few weeks we were rewarded with a reduction of the tissues and an entire freedom in nasal breathing, and a cure of a permanent character.

Since then I have practised incisions and punctures in every case in which there was a contra-indication to the more radical measures which we ordinarily use. The latter cases are numerous, embracing those in which the galvano-cautery is objected to, and in which the small saw and scissors or snare are repugnant to the mind of the patient who is suffering from one of the various intra-nasal deformities resulting from or concomitant with the different stages of inflammation and hyperplasia so commonly seen connected with catarrhal diseases of the naso-pharynx. There is a class of cases, an example of which is seen in the following taken from my case-books, in which this mild measure is especially appropriate and efficacious.

Miss S. M., of Pittsburgh, referred to me by one of our New York colleagues, with catarrhal disease of the naso-pharynx. She was the only remaining child of wealthy parents, who had lost a number of grown children, and were consequently not only nervous and timid about any measure that appeared at all severe, but the lady herself was a very frail person, and subject under the slightest cause to serious fainting spells, that confined her to bed and left her heart's action weak for days at a time.

The chief but not the only cause of her naso-pharyngo-laryngeal catarrh was an extensively thickened septum, from chondritis. Upon its plane, in the left naris, the adventitious tissue filled the cavity to stenosis. The saw was forbidden, even to be mentioned, or any other of the severer measures of like nature, and only the milder incisions with the knife were resorted to surreptitiously, until the sight of blood following my examination became a thing usually looked for, and it was attended with constantly increasing benefit. I finally showed her that the innocent-looking handle, on the end of which was wrapped a piece of cotton, that I used ostensibly to cleanse the surfaces, really concealed the blade of a small knife, with which I made as many punctures deep down into the inflamed tissues as I could at each sitting, without exciting suspicion on the patient's part or producing any mental impression that would

bring on fainting. These incisions were at length known to the patient and agreed to, and the gradual but sure result was a reduction of the hyperplasia upon the septum narium, curing the concomitant catarrhal disease in the pharynx and larynx; but most of all to be noticed was the improvement in the general health of the patient.

This, gentlemen, is a type of case and the style of treatment of which I could give you a very long and somewhat varying list from my case-books; and now, after several years' experience, with this milder form of surgical measure, I bring the simple plan to your notice, believing that, even if many of you have already used it, it will not be altogether amiss for me to attest its value in this brief recital of actual experience.

THE PREVENTION OF CONCEPTION.

BY ISAAC PEIRCE, M.D.,
TAZEWELL, VA.

There are questions which perhaps it is better for men never to discuss, questions the discussion of which will teach nothing and which should be weighed by the individual conscience and decided within the secret workings of the individual mind. But since such a journal as the REPORTER has opened the question of preventing conception, we can but believe that good will follow its discussion, and thinking men should enter the argument with minds unbiased with what has heretofore been regarded as the moral or religious aspect of the question. Moreover, if we enter this subject at all, we should do so with perfect candor, calling a spade a spade, trying to further the good of our science, and not seeking for something about which to multiply words, never reaching a conclusion. The appearance in the REPORTER of any communication on a subject so fraught with interest to physician and patient alike, invests it in the natural order of things with much weight; therefore those who undertake such communications should see that they have considered their subject well before expressing decided opinions.

At the date when I write, there has appeared but one paper on the subject since the Editorial which prompted it—that of Dr. Blackwood, who enters directly into the argument of the question and deals out facts and opinions with a fearless hand. His courage and candor deserve admiration; but I think he is too hasty in some of his conclusions and in some respects misses the spirit of the discussion, as well as the end to be accomplished. As I see it, the question suggested by the Editor was not how to prevent criminal abortion, but conception. Every man knows the horrors of illicit love and the suffering of misguided though patient and confiding women; no man is insensible to the lifelong shame of a child thrown upon the world without knowing a father; and no man denies the wickedness of criminal abortion. No medical man doubts the suffering, and in many cases permanent injury, of the woman who practises abortion that she may escape the shame of her own wickedness, sinning doubly that she may shield herself and her destroyer from the condemnation of the world. No, it takes no one to tell us this; we all know it too well; the poor creatures come to us almost every day, broken down in health, asking for treatment, asking that their secret be protected, and are willing to undergo anything to relieve their physical suffering and escape the consequences of their error. There are others known to us who are in a worse condition, those who yield to the seducer's embrace, bear their children, and, losing all respect for self, plunge into the depths of misery and disease, becoming of those to whom Mr. Leckey thus alludes in his History of Morals in Europe: "That unhappy being whose very name is a shame to speak, who counterfeits, with a cold heart, the transports of affection; scorned and insulted as the vilest of her sex, and doomed, for the most part, to abject wretchedness and an early grave, she is in every age the perpetual symbol of the degeneration and sinfulness of man; she remains while creeds and civilizations rise and fall, the eternal priestess of humanity blasted for the sins of the people."

Now, knowing the state of things as the members of the medical profession do, and having exerted every effort toward a remedy, is there a possibility of bettering these conditions by preventing conception, as Dr. Blackwood intimates? I say No! I think it can be made plain to every man that we would but bring about a worse state of affairs, if it is possible to imagine anything worse. It is true we may prevent criminal abortion, we may lessen suffering, pauperism, and neglect among children the issue of illicit love; but we do more, and we should look at this side of the question. Is it the woman, who in the hour of her fall thinks of conception? Does a preventive suggest itself to her? Does she dream that this act will

crown the love and trust she has given her seducer before the hour of its perpetration? Or is it the man, who, knowing his vows of love and marriage to be false, plans her fall and studies the question of a preventive? In eight cases out of ten, I think it is the man; and, with a sure preventive in his hands, how much stronger will be his argument, how much oftener will his persuasion meet compliance, and we all know how the falsity of his promise of marriage will increase. In the other two cases, it will require no offer of marriage, no vows of love; the desire and the preventive will be all that is required to carry them from the arms of one lover to those of another.

If Dr. Blackwod is right in teaching that a man is not culpable before the laws of God and man who interferes to prevent gestation *before* conception has occurred, as I see it, he will institute a new moral law which will be entirely different from that taught by any period of the world's history. He would make adultery a matter of no consequence so long as conception is prevented with its attendant ills. I think I am just in this view, as I think I have ground for my fear when I shudder at what would be the result of the promiscuous prevention of conception, even with the idea of stopping criminal abortion, pauperism, and suffering of illegitimate children. I believe that if we put into the hands of men a ready and sure means of preventing conception, there will be more prostitutes, fewer marriages, and more disease among women. Syphilis, gonorrhœa, and chancroid will be the next in order requiring a preventive.

I think this is the idea which has kept the question in the dark so long, and not the fear of how moralists and church people would receive it. It has been the fear of instituting a process which we could never hope to control, and which would in a short time become so universal and popular as to admit of no check, that has made cowards of the medical profession. I think we have been cowards heretofore, and the REPORTER will deserve much credit if this discussion should determine for us clearly the questions: Should we ever prevent conception? and, if so, when should we interfere? What is a ready and sure means of effecting the object? and how shall we keep the matter in our own hands? No physician should give a preventive to be used outside of the married state, any more than he should produce abortion for the sake of shielding either mother or father. And if we confine ourselves to married life, a vast number of men, both in and out of our profession, will take the ground that, child-bearing being the natural consequence of matrimony, it would always be wrong to interfere; that a woman who incurs the risk of pregnancy and childbirth should bear it as best she may, never crying out, no matter how great her suffering, always allowing her husband his "rights"; and if she fill a premature grave they would consider it a sad fate, but a fate from which there is no escape. Then, a large number of women who have safely passed their menopause are prepared to laugh at the suffering of their younger sisters, and would look upon any interference as criminal. The younger ones would show a majority on the other side, and some, as in Dr. Blackwood's case, will cry out that suicide is preferable to another pregnancy and delivery.

Assuming that there are cases—and I think few men in the medical profession will not admit that there are cases—where the prevention of conception would restore the happiness of a family, give peace to the wife, turn the husband again to the path of virtue, and prevent the life-long suffering of offspring; then the question arises, what are these cases? Dr. Blackwood is right in claiming that there is no justice in condemning children to an inheritance of syphilis, scrofula, tuberculosis, epilepsy, or imbecility, and he might have added a host of others. Where this is to be avoided, I agree with him that prevention is *imperatively demanded.* Again, women who are deformed, women whose lives are made one constant and heavy burden by pregnancy so often repeated that they seem never to have an end, women who are made miserable by the so-called "habit" of abortion, and women whose former gestation and delivery have brought them almost to the door of eternity and who are now in constant dread lest another such ordeal will complete the work and leave a motherless child or children—yes, all these women who are crying out to us from the depths of their fear and misery for help should be heard and their prayers answered. There is no other way. Men *will not* abstain from sexual intercourse, though they see their trusting wives gradually slipping from them, and if here and there one is found who yields to the entreaties of his wife to spare her from a horrible death and a premature grave, he will most often be one who is damning his own soul, ruining his life, and saving the woman from one evil only to render her more unhappy by gratifying his lust among harlots.

Recognizing the fact that there are cases in which prevention is a necessity, and that our duty is to work a reform that will prevent much of the physical suffering and mental distress among women, I am at a loss to know what are the means best suited to accomplish this and how to apply them. The number of preventive measures which have been proposed is not small, but the selection of one which we can control and its restriction to those alone who really need it are not easy. Let it become generally known that the medical profession countenances a preventive even in a few cases, and there is reason to fear this will be stretched to a license which will work much mischief to women who are already experimenting in this direction, who have no reason why they should not fulfill the God-given function which makes happy homes, and who are now only held in check by the judgment of the world. Will it not also place in the hands of men a ready argument with which to destroy the purity of loving, trusting girls? As I see it, this is the reason why to the deserving as well as the undeserving we have for so long given the old woman's advice, "to take a glass of cold water before going to bed and *nothing else.*" This is the reason why we have allowed women to lead lives of misery and seemed not to heed their cries for relief. Thoroughly awake to the fact that the prevention of conception is sometimes right, that it is sometimes a plain duty, it is to be hoped that we may yet find some means whereby we can overcome the difficulty of the problem and confer a blessing on those who will appreciate it most.

A CROP OF BOILS.

BY WILLIAM M. CAPP, M.D.,
PHILADELPHIA.

Quite a number of articles have recently appeared in the medical journals concerning furuncle. Each writer had his favorite "sure cure," and one might feel that there was cause to reproach himself as blameworthy if he did not at once abort, cure, prevent recurrence and avoid a "crop of boils" in any case of the kind which should present itself. Lately an opportunity offered itself to me to try some of the remedies advised. A patient about seventeen years old came for treatment for an unmistakable boil upon the thigh—large, inflamed, swollen and painful. The general health was good and at first only local applications were resorted to. Mindful of the theory that succeeding boils come from external inoculation from a previous one, the greatest cleanliness was observed and boracic acid disinfection was used. A liberal application of a salve composed of salicylic acid rubbed up in simple cerate was made at bedtime, and though it caused smarting at first, afterward it was soothing, and a good night's sleep was obtained. In the morning there was a large accumulation of matter, which was removed without much pain; but the skin in many places around, where it had been covered by the salve, was blistered as thoroughly as if cantharides had been used. The hardness was all gone, there was relief from pain and very soon there were the appearances of a healthy sore which healed satisfactorily. But a few days later as many as nine other points of pain and induration were noticed, all within a radius of five inches from the site of the first boil. The same application but with a smaller proportion of acid, and with cosmoline substituted for the cerate, was used. The boils all quickly suppurated with very little pain. Most of them were superficial; two only were at all large and none of them were as formidable as the original boil. They were thoroughly cleansed by a solution of bi-borate of soda and dressed with cosmoline of neutral reaction, having boracic acid rubbed into it in about the proportion of twenty grains to the ounce. Some cosmoline has an acid reaction, and hence is irritating and for such applications is better avoided. This treatment proved soothing, at once allaying the itching and soreness, and a rapid healing followed with no further irruption in that locality.

A few days later several inflamed pimples appeared on the face and the general health appearing a little depressed, an iron tonic was administered and also sulphide of calcium, four times daily in a dose of three-quarters of a grain, which was gradually increased to a grain and a half. One of the pimples becoming large and painful, another of the remedies recommended as infallible was tried upon it, viz.:—tannin made into a paste with tincture of arnica and gum acacia, painted thoroughly over and around the affected spot. It certainly was soothing, but otherwise worthless, unless indeed it may have hastened suppuration; for, the next morning the boil discharged copiously.

By this time several angry lumps were developing, with much pain, on the cheeks and one on the chin. As there were still other treatments recommended as never

failing to abort a forming boil, it was thought desirable to try some of them. The chin was freely and frequently bathed with a solution of salicylic acid—the part kept moist with it. It was soothing, but the boil suppurated at three points, with probably less swelling and pain however, than otherwise might have been expected. A strong solution of boracic acid in alcohol, which was much praised by a recent writer, was tried upon another forming boil, with quite similar effect.

The two upon the cheek which threatened to be very troublesome were treated according to the recommendation of still another writer. They were painted freely for three days with the semi-fluid extract of belladonna, at the end of which time they had nearly disappeared without suppuration and were practically well. The application from the first was soothing and the result satisfactory.

In addition to the treatment narrated the patient took at the solicitation of friends as a vaunted household remedy for boils, some porter—a wineglassful four times daily for three or four days. After about four weeks from the appearance of the first boil, there were no further manifestations and the malady seemed passed.

It is in order now to decide if any of the remedies had any effect whatever upon the disease except to mitigate the pain at the time. The writer feels that in treating another case of furuncle, unless meanwhile a better course should commend itself, he would rely upon calcium sulphide internally and belladonna externally, and would hope for like good results.

Since writing as above, an acquaintance relates that quite recently in treating a case essentially similar, the medication used was the fluid extract of burdock internally, with equally good results. This remedy then, in his estimation, is also to be added to the list of "sure cures."

—Prof. Heinrich von Bamberger, of Vienna, Austria, is dead.

—The *Northwestern Lancet*, Nov. 1, 1888, says that the mortality from fever among the workmen on the Panama canal has been greatly reduced by the establishment of proper hospitals for the care of the sick, and a convalescent home on one of the islands in Panama Bay. It is said that as the result of these measures workmen no longer stand in dread of the fever, and are flocking to the work in immense numbers.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 1, 1888.

The President, A. Jacobi, M.D., in the chair.

Dr. J. Lewis Smith read a paper on

Sudden Heart-Failure in Diphtheria.

Physicians of experience, he said, commonly meet with cases of diphtheria which seem to be progressing favorably; the medical attendant and the relatives of the patient feel cheerful at the bright prospect of recovery, when suddenly the scene changes, symptoms of dangerous heart-failure appear and usually result fatally. In the more favorable cases active stimulation may cause the patient to rally, and perhaps to recover; but often another attack occurs and ends in death. The most complete clinical history of sudden heart-failure in diphtheria has been given by Cadet De Gassicourt. In some cases the symptoms develop more gradually. In the first class the patient's pulse is likely at first to be slow, then becomes rapid, the respiration superficial, the surface pallid, perhaps slightly cyanotic, the patient utters cries of agony, and soon dies, or perhaps rallies under stimulants, but succumbs to a subsequent attack. In the second class of cases death is less sudden; there is no agonizing cry or moaning at the last moments. Some, perhaps the majority of patients, manifest disturbance of the stomach, epigastric pain, vomiting, dyspnœa, rapid respiration and heart-beat. De Gassicourt has recorded but one recovery in fourteen cases A careful microscopical examination has been made in three cases, including an examination of the pneumogastric nerve and myocardium, which were normal in one case; in all three the medulla oblongata was apparently normal, but the gray matter of the cord which had no immediate connection with the affected heart contained degenerative changes. Sudden loss of power in the heart has been attributed to several causes; for instance, to changes in the muscle of the heart; to thrombosis or antemortem clots in the heart; to disease of the central organ of innervation, the medulla oblongata; to deficient conducting power in the pneumogastric; to the influence of ptomaines.

Recent observations have not borne out the view that endocarditis is the cause of the

cardiac failure; its existence has not been proved. A more probable theory of the cause is that granulo-fatty degeneration occurs, a change which is present in some cases, but can account for only a few.

Cardiac thrombosis has been regarded as a cause by Beverley Robinson and by French writers, but it has since been shown that the clots are identical in appearance and kind with those found after death from other diseases; they occur during the death-struggle and are secondary to heart-failure. The theory of deficient innervation is most applicable to the majority of cases. On this theory also one can account for vomiting, epigastric pain, and interference with respiration—the lungs, heart, and stomach being supplied by the same nerve, the pneumogastric

The facts, Dr. Smith thinks, justify the view that there is a cardiac paralysis. What is true regarding the nature and cause of palatal and multiple paralysis is probably true of cardiac paralysis. He advanced objections to the view that the cardiac failure is due to peripheral neuritis; when the neuritis exists it need not be the sole cause. As to disease of the central organ of innervation, he said it has not been demonstrated. The mutability of the paralysis, its disappearance and reappearance in the same muscles, conflict with these views of its origin.

A theory regarding the etiology of diphtheria and its symptoms which is rapidly gaining ground is, that the specific germ acts locally, and that the systemic infection takes place through ptomaines the product of such germs. Treatment must be prompt and with active remedies. The patient should be kept quiet in bed, the head low. Alcoholic stimulants should be administered, and concentrated and peptonized food be employed; hypodermic injections of brandy should be given during the sudden seizure. Other useful agents are: ammonia, camphor, musk, the electrical current. Subsequently, remedies employed in diphtheritic paralysis of other forms may be used. Some have spoken very favorably of strychnia.

The PRESIDENT thought the paper suggested the following points for discussion: Is heart-failure occurring early in diphtheria of the same nature as that occurring late? Are the cases with a slow pulse identical with those with a rapid pulse? Are the cases following general paralysis the same as those preceding it?

DR. A L. LOOMIS said he had made a post-mortem examination in but one case of diphtheria with death from heart-failure. The right cavity of the heart was much dilated, its walls flabby and granulo-fatty. He had supposed that sudden heart-failure in diphtheria did not always depend on the same cause. His impression is that in the acute stage of the disease it results from the diphtheritic poison, whatever that may be, just as heart-failure sometimes occurs from the poison of typhus fever In other cases he said he had rather yielded to the opinion that it is due to a peripheral neuritis.

DR. CAILLÉ said he had formerly advised patients with mild diphtheria to be out some, and take light exercise in the fresh air, but one patient having had heart-failure under such circumstances he now always advises the patients to remain in bed. One of his patients brought on heart-failure and death by taking some indigestible food. He advises in all cases of diphtheria, rest in bed, proper food, and stimulation.

DR. BEVERLEY ROBINSON referred to his investigations regarding diphtheria while he was in Paris a number of years ago, when he made many post-mortem examinations and found heart-clot of a nature to convince him that it was antemortem and the cause of death. He has not had reason to change the view then formed. He raised the question if the common free employment of tincture of the chloride of iron may not be a cause of such ante-mortem heart-clot.

DR. FRUITKNIGHT leaned toward the view that ptomaines, the product of microbes on the surface, are the toxæmic agent and cause of heart-failure in diphtheria.

DR. SEIBERT said he would differentiate between heart-failure from the effects of the diphtheritic poison on the central nervous system in the acute stage of the disease, and that occurring later and usually in gangrenous diphtheria.

Dr. Dessau made some remarks, and Dr. Loomis combated the view of Dr. Robinson as to heart-clot causing death. He expressed the belief that such clots develop during the death-struggle which is caused by heart-failure.

The PRESIDENT mentioned anæmia of the brain as one cause of sudden death in diphtheria, as it is in other diseases which leave the patient in a weak state. He also said that in some cases the heart-failure may have received the credit of causing death when really paralysis of the respiratory muscles has been the occasion of it. He suggested the freer use of alcoholic stimulants in diphtheria; he thinks there is little likelihood of their too free administration.

Dr. Smith, in closing the discussion, suggested that cases in which the patient, almost moribund from heart-failure, is rallied for several hours or a day before having another attack followed by death, are against the theory of heart-clot, as, indeed, are cases of multiple paralysis.

Reports of Clinics.

BELLEVUE HOSPITAL.

MEDICAL CLINIC—PROF. LOOMIS.

Gout.

Case I.—The patient was a man, 42 years old, a barkeeper by occupation, and a well-nourished and healthy-looking man. He was brought before the class with the history of having been acutely sick for four days. In speaking of his history to the class, Dr. Delafield said that he gives no family history of gout. He has always been a drinking man, indulging in all sorts of drinks, averaging twelve to fifteen a day. He has been also a hearty eater, eating rich and nutritious foods. For many years he has not taken any active exercise, none at all out of doors. His first attack came on about fourteen years ago. In previous good health, he awoke one morning to find the great toe red, swollen, and very painful. These symptoms increased for the first few days, the pain being most severe at night; and then these signs subsided, leaving him perfectly well. The duration of the attack was about one week. He remained in good health for about one year, when he was again suddenly seized with an illness similar to the one just described. The same joint was affected: the acute signs lasted, as before, four or five days, but the toe remained stiff and tender, and he could not go about well for nearly two months. After this, the attacks increased in frequency; other joints became affected—the fingers, elbows, knees, shoulders and hips; and, during the interval between the acute exacerbations, he was never entirely free from stiffness and soreness in certain locations. At the present time, there is a typical swelling at the knuckle of the index finger of the right hand, and also at the joints of both big toes.

This, then, is a characteristic case of gout. The one exceptional feature it presents is the fact that there is no history of hereditary taint. Gout is a disease that is almost always hereditary, and further, that usually requires more than one generation for its development. A gouty parent is certain to give the gouty diathesis to his children. But in this patient there is no such history, and we look to the fact that he has been almost all his life in-doors, eating largely and drinking largely—especially of wines and ales—to find the cause of his disease. A man cannot develop gout in one generation on wine alone: it can occur only in those who eat more than they can assimilate, and at the same time do not take sufficient exercise.

Dr. Loomis asserted that one-third of those listening to him at the Clinic ate more than they could assimilate, and, as in the patient, this excess is taken up by the blood. In the present case, uric acid is generated, and in the joints urate of soda deposited, and this must occur unless exercise uses up this excess from the food. Dr. Loomis does not believe in the existence of rheumatic gout; the disease is either the one or the other, rheumatism or gout. A patient may have an attack of rheumatism, and later on he may also have gout, but there is no combination of the two diseases.

Gout, as it becomes chronic, in all cases, as in this one, makes its victim a cripple. In an acute attack, the first change in a joint is the deposit of urate of soda on the fringes and edges of the cartilage; accompanying this there is hyperemia, etc. At first, these deposits are removed after the attacks, but later on they remain and thus incapacitate the joint. Similar deposits may occur all over the body, and may be seen in the joints, skin, ear, eyelids and elsewhere. The present case he believes to be the earliest in regard to development he has seen in non-hereditary gout. Where this tendency is strong he has seen the disease manifest itself in children of five and six years of age. In this patient it began, as it always does, in the big toe. As is almost always the case, this patient has refused to give up his mode of living. He loves his table and he seasons his food highly. The gouty subject is a *bon vivant*, and it is always a pleasure to dine with him. In this lies the difficulty of weaning these people from this active cause, over-feeding. In the treatment of these cases little can be expected from local applications; but the limb should be well elevated, and colchicum should be given. It is to this drug that entire treatment is trusted. It will not cure gout, but it will relieve an attack, and that is all. It makes these chronic cases worse. These sufferers pin their trust to some one preparation and

carry it about with them, to be taken on the first appearance of an attack. In this way an attack can be often warded off. There are Laville's Liquid, Blair's pills, White's pills, and a host of other remedies, among which is the one that this patient has had faith in, namely, Loomis's Acetic Extract of Colchicum.

Dr. Loomis long ago found out that there is but one preparation of colchicum which is of very much value in acute gout, and that is the acetate of colchicum. Laville's Liquid used to be employed in England and elsewhere for years in preference to every other drug in these cases. None relieved so rapidly and completely. This was due to its containing, as the chief ingredient, this acetic extract of colchicum. This drug will certainly relieve, if carried far enough—it should purge sharply two or three times—in this manner the capillaries of the portal circulation are unloaded. To assist in this effect other drugs can be added. Loomis's preparation before mentioned contains also aloes, ipecac, and calomel. Dr. Loomis suggested the following gout pill:

℞ Ext colchici acetici,
Ext aloë,
Pulv. ipecac.,
Hydrarg. chlor. mit. . . . . āā gr. i
Ext. nucis vom. . . . . gr. ¼ ad ½
M. Sig. Ft. pil. No. I. To be taken every four hours, until it purges.

These pills may be carried about and employed at the first sign of an attack: they will often abort it.

After the attack is over, the real treatment begins. Medicines are now of no avail. Iron does harm. Cod liver oil is not usually well borne.

Our dependence is on diet and exercise. On the question of diet the profession is divided. One-half say, Give the starches and no meats; the others, No starches, but green vegetables and meat. Dr. Loomis believes it makes but little difference, and employs in his own cases a mixed diet; but it must be very sparing, attention being directed to the thorough assimilation of all that is eaten. To achieve this purpose the patient must be half starved: he should always rise from the table hungry. His wines and his high living should be stopped. If for any reason stimulants should be required, spirits is the best form to use. Active exercise in the open air is also of vital importance. He would advise this patient on his recovery to become a cow-boy.

Having occupied so much time on this first case, there remained but sufficient to present the second and note the chief distinguishing features between the two.

Rheumatism.

Case II.—The patient was a man, 35 years old, a worker in a gas-house, where he is exposed to sudden variations of temperature. This patient was attacked suddenly several days ago: his right hand is now much puffed up and red, his left wrist is also affected, and there is some pain and swelling in the right shoulder. He gives no family history of rheumatism. He is a moderate drinker, and this is his first attack.

Briefly, the differences between this case and the preceding one are these, and they are characteristic: Rheumatism never begins in the smaller joints, and in one attack joint after joint will become affected. The reverse is true of gout: it begins in the smaller joints, and does not pass from one joint into another. Rheumatism is liable to give acute endo- and peri-carditis. Gout is not likely to, but it may develop slowly an interstitial inflammation of the peri- and endo-cardium.

The subject of rheumatism has been under the influence of damp and wet, or as in this patient, of sudden variations in temperature: the gouty subject gives a long history of no exercise and hearty feeding. And it is just here in the etiology that is found the greatest difference between the two diseases. A person of this patient's age will probably have some cardiac complication before his attack is through. On examination, a murmur was discovered with the first sound of the heart.

These cases of endocarditis usually leave a crippled heart behind them.

—The *Quarterly Journal of Inebriety*, October, 1888, says that the Count de Villeneuve was tried at Hyeres, France, for selling wines adulterated with arsenic. It seems several persons, noted wine drinkers, had died, having many symptoms of arsenical poisoning, and others were made very ill. The wine used was found to be heavily charged with arsenic to hold it from change, and was the direct cause of the death and illness. The trial was for damages by the friends of the victims, but the prosecution failed. The judge condemned the process of wine adulteration and the case ended. A curious sequel to this event followed in September last, when the Count de Villeneuve gave thirty thousand francs indemnity, and two plantations, to over two hundred of the sufferers who had drunk this wine.

SPECIAL CORRESPONDENCE.

JOTTINGS FROM AROUND THE WORLD.

The University of Melbourne.—Examination Questions.—Boarding Houses for Students. Visit to a Lecture-Room.—Law Against Immoral Literature among the Fiji Islanders.

MELBOURNE, Sept. 10, 1888.

My travels have been so extended, since beginning the "Jottings from the Occident," that I feel compelled by longitudinal reasons to change my title; and as I propose to complete the tour of the world, *via* Indian Ocean, Red Sea, England, New York, and finally San Francisco by the way of the Isthmus of Panama, it will be more appropriate to name these papers as above. I trust I can jot down such medical items as, gathered by a physician in his wanderings, will be of interest to many. It has been gratifying to me, and also shows the wide circulation of the REPORTER, that a number of letters have reached me from doctors all over the country asking fuller particulars of some points touched upon, especially in regard to California. It will give me pleasure to answer any questions.

Australia is no longer in the occident; the English include this country in the orient; but it is the dividing line between the occident and the orient—Honolulu is in the far occident to them, and Melbourne in the far orient.

University matters in Melbourne are of sufficient peculiarity and interest to make this letter deal almost entirely with them. There is a flourishing medical school in this city, a department of the University of Melbourne. The corner stone of the University was laid in 1854; the medical department was formed in 1862. The grade of study is a high one; since 1872 no student can obtain credit for any portion of the medical course unless he first has passed an examination in Greek, Latin, English, arithmetic, algebra and geometry. The course continues five years, and the student must pass five examinations during this time; then, if successful, he obtains the degree of Bachelor of Medicine or of Surgery, as the case may be. The examinations are both written and oral. A graduate from any recognized school of medicine may obtain the University degree after passing the fifth-year examination. Candidates for the degree of Doctor of Medicine or of Master of Surgery must be Bachelors of Medicine or of Surgery of at least two years' standing in the University of Melbourne or in some other University recognized by it. I wish that space would admit of making an extended list of questions asked at the fifth-year examination. I shall give simply a specimen in each department: "What are the effects on a pigeon of removing the whole of the cerebral cortex?" "Give the minute anatomy of the œsophagus." "Describe the macroscopic and microscopic changes which occur in acute bronchitis." "Write a commentary on adenomata." "Describe all the structures that bind together the bodies of the vertebræ from the axis to the sacrum." "Describe the steps of the dissection necessary to expose the inferior dental nerve." "Compare the hearts of a frog, a fish, and a mammal, and make a sketch of each." "Dissect the nervous system of a crayfish." "How may aldehyde be prepared?" "What are the different forms of cannabis Indica?" "Discuss the dietary of acute febrile disease." "Enumerate all the appearances of drowning, twenty-four hours after death." "What are the diseases that may produce cavities in the lungs?" These questions are for what are called the ordinary examinations; if any student enters for an honor examination, a separate set of questions is used and is correspondingly more difficult.

A word as to the building itself. Both the University building and the medical hall are unattractive—rather musty, ivy-grown affairs that would look all right in England, but are not quite up to our modern ideas in newer countries. The grounds are, however, very large and very pretty, being adorned with flowers, trees of all kinds, and an artificial lake.

The professors can neither sit in Parliament, nor become members of any political association, nor can they give private instruction, nor receive any persons, whether students or otherwise, as boarders in their houses. A curious feature is the license required to be obtained by all who desire to keep a boarding house for students. Those desiring to obtain a license must make an application in writing, accompanied by the certificates of two or more resident householders in Melbourne (one of whom must be a member of the Senate of the University, or a justice of the peace) as to the character of the applicant. On the receipt of such an application the Registrar inspects the house of the applicant, and reports to the

Chancellor as to the situation and neighborhood, the accommodation, the state of repair, and the general fitness of the house for the purpose, and any other remarks he may consider for the interest of the University. Upon the payment of one pound the successful boarding house is granted a license for one year. Any breach of conduct on the part of this house will result in a revoking of the license or a refusal to renew it. How many of our poor boys in Philadelphia would like a plan like this. I think many fewer "*mysteries*" would be served up at dinner. And what glorious fun to hint, in the most dignified tone of voice, that an immediate change must take place in the *menu* or "we shall tell on you." And still more, as I am writing this, my doctor-friend beside me says, the house thus under the ban of the college is published in the most prominent paper of the city.

I had the pleasure, a few days ago, of taking luncheon with the Dean of the Medical faculty, Prof. H. B. Allen, and of hearing two of his lectures on anatomy and pathology. The Doctor's life has been a University one; first as student and graduate, then as lecturer, demonstrator, professor and dean. He is only about 40 years of age, but the present status of the medical department is largely due to his faithfulness to its interests. The salary of the professors amounts to about five thousand dollars, and a house free. A new house has been completed for Dr. Allen in the grounds and next to the school. The money for all University purposes is voted by the Victorian Parliament; only a few private bequests at present have been received. The Professor says that while there is no direct law against private practice, they find that accepting a chair is equivalent to retirement from practice; the duties are so many and so continuous, by reason of the graded courses, that it is impossible to do anything but University work. A Chair is not the stepping-stone to practice here; quite the reverse. The position is made to compensate for this in two ways; first, by making the position a sure one—a professor can be removed only on the showing of gross misconduct, and he can demand reasons of removal, even before the Supreme Court if he deem it best; and, in the second place, after fifteen years' service a very handsome extra is added to his salary, on the ground that by this time his services in practice would be yielding a larger income.

A few minutes before the Professor arrived I entered the arena of the lecture room in company with Dr. Gillam, a recent graduate of the University of Pennsylvania, who is out here in charge of a patient of Dr. S. Weir Mitchell. We found that medical students are the same the world over, as we were received with most hearty applause, on the simple basis of anything for a noise and a racket. But on the entry of the Professor, instantly the most profound quietness prevailed, making a strong contrast to some of our similar occasions at home, where the unbounded delight of the professor seems to be to hear the greatest commotion on his appearance. There was a dignity and respect in this instant hush that impressed us.

In front of each seat is a table for note taking, which is insisted upon. The lecture was on the anatomy of the spinal cord, and was most excellent, showing that the lecturer was a true teacher; self was entirely hidden and the sole effort was to make clear the subject in hand. There was not the slightest hint of personality, all was for the one object—teaching. After the hour was over the Professor retired for a few moments, during which time an advanced class had assembled in the same room to hear the lecture on Pathology, the subject being heart diseases. In this lecture the doctor spoke very slowly, and waited for each word to be taken down. At the close of each lecture the roll was called and absentees marked; an average attendance of eighty-five per cent. being required. After the close, I took the opportunity of making a further interview, and learned the additional facts that the average number of graduates is twenty-five a year, usual attendance one hundred and fifty; no native Australian has ever taken the degree; the clinical service is not in a satisfactory condition; no clinics are held in the University grounds, the students attending the Melbourne hospital. In this line Prof. Allen is striving to make some reforms and advances. While a foreigner must be impressed with the thorough and exacting theoretical courses, he can readily see that our country is far ahead in clinical teaching. The clinic room is scarcely ever the preparatory process for higher professional position, therefore it is not so eagerly sought after. The diplomas of only such colleges as have a positive three-year graded course are recognized here; it is not sufficient to show that the applicant has studied medicine for three years. A case in point has just been before the Registration Board. An American claimed the right to practise on account of having taken an extra year a few years after his regular two-year

course in one of our best colleges; his claim was rejected.

There is no chair of Sanitary Science as yet in the University, but steps are being taken now to create such a one, and the Government has indicated its willingness to furnish the money. The Government is very liberal to its University; Prof. Allen says that he received word a short time ago that, the budget being in a satisfactory condition, they would like to know how much money he wanted for the next ten years for the University; he named a goodly and increased sum over the usual amount, and it was at once voted.

The great Centennial Exhibition which is going on here now, while of the grandest proportions and showing the rapid growth of a most wonderful country, is not of sufficient medical interest to cause any special remark on my part in a medical journal. There is nothing on exhibition that is specially new in our line; in the American Court the medical display consists of several notorious patent medicines, and throughout there is a dearth of any worthy medical exhibit. For reasons given in a former letter this would have been a favorable opportunity to show these people anything of a sanitary character—systems of drainage, etc., etc.

Fiji islanders and skull soup seem to be closely associated in one's mind, the readings of school days having fixed the cannibalistic tendencies of these people in the memory. What will you think when I tell you that, quite recently, the authorities of these islands confiscated some of Naphey's books, as being literature calculated to spread immorality? I am personally acquainted with the man who tried to import them; he was arrested, his books taken out to sea beyond the coral reefs, and dumped into the ocean; he was saved from imprisonment only on the promise that he would never do such a thing again. Some of the poetry of this "goody goody" is taken away when we know that the very prosecutor in this case lives down the island with three or four black wives. One of the officials who obtained a glance at one of the books, with an imagination fired by the fuss made over the matter, determined to have one at any risk; he made known his want to my friend, who took his revenge on the Fijians as follows: he had one of the books unbound, and then had it rebound with the attractive title of "A Family Dictionary of the English Language"; it passed the customs as such in safety, and the official is happy.

PERISCOPE.

Angioma of the Forehead.

The *Revista de Ciencias Medicas*, of Havana, August 20, 1888, contains an account of a case of angioma of the forehead which was successfully treated by electrolysis. The patient, who was under the care of Dr. Raimundo Menocal, was a little girl 2 years old. The tumor, which was of the size of a large filbert, was smooth and soft; it was of violet color, and could be reduced by steady pressure. It had appeared soon after birth, and was growing gradually larger. Elastic compression had been tried without result. On August 6, Dr. Menocal applied electrolysis, introducing the needles in various parts of the tumor, but always with the points toward the centre of the mass. The application, which was continued for three minutes at a time, was repeated every three days. The tumor was somewhat diminished in size after the first sitting; at the fourth, eschars were observed about the negative pole, which were thrown off a few days later. This was followed by a little suppuration, but there was no hemorrhage. At the date of the report no trace of the tumor remained except a few tiny scars.—*British Medical Journal*, September 15, 1888.

Hysterical Neurosis of the Stomach.

J. Schlesinger (*Wiener med. Blätter*, No. 3, 1888) communicates the case of a young girl who suffered with disturbance of the stomach which was diagnosticated ulcer, although there was no hæmatemesis. She recovered completely under a milk treatment rigidly carried out. One year subsequently the patient was again taken sick, with violent pain in the stomach, loss of appetite, nausea, vomiting, and complete sleeplessness. No kind of food could be borne, and the largest doses of morphine, even when administered subcutaneously, had not the least effect. The diagnosis of ulcer of the stomach was then made. It was learned, however, that in the boarding-house in which this patient lived was a girl affected with hysterical neurosis of the larynx, and that in a short time two other young girls, including the patient, became similarly affected. A diagnosis of hysterical neurosis of the stomach was then made, the patient put upon bromide of sodium, and complete recovery soon occurred.—*Centralblatt f. d. med. Wissenschaften*, Sept. 1, 1888.

New Use for Bergeon's Method.

We learn from the *Wiener med. Presse,* August 26, 1888, says that Givre has recently communicated to the *Lyon Médical* a very interesting case which suggests a use for Bergeon's method of rectal insufflation of gas that may prove of more practical value than the one for which it has heretofore been used. It seems that a lad fourteen years old was attacked on May 23 with obstinate obstruction of the bowels, accompanied with vomiting of fæcal matter and colicky pain in the umbilical region. As the condition remained unchanged on May 28, the patient was brought to the hospital Hôtel Dieu, where his symptoms were found to be enormous meteorism, small pulse, superficial rapid breathing, temperature 101.3°, fæcal vomiting, violent colicky pain, and obstinate obstruction of the bowels. After copious irrigation, washing out of the stomach, and the constant current had been employed in vain, the rectal injection of gas according to Bergeon's method was tried. The tube was inserted into the rectum to the extent of fourteen or fifteen inches, and the gas injected under very high pressure. When the belly could be distended no further and the contour of the inflated coils of intestine was clearly visible, the patient was seized with violent pain and the tube was withdrawn. The patient had at once a desire to go to stool, and passed with a loud noise the enema of gas, and then from six to eight quarts of yellow, stinking fæcal masses. The patient has since been well.

Aneurisms of the Aorta.

In a communication to the Academy of Medicine of Paris, August 13, 1888 (*Gazette Hebdomadaire,* August 17, 1888), Germain Sée stated that he had had in his practice twenty-four patients with aneurism. He has noticed that these patients very often become tuberculous and die of a phthisis which is characterized by cavities and a progress that is slow and non-febrile. This fact seemed to him interesting from the point of view of the pathogeny of the disease in these patients.

In speaking of the action of the iodides in aneurism, M. Sée expressed the opinion that they have a definite action (1) upon the dyspnœa of secretory origin, by liquefying the product of the catarrh; (2) upon the intra-pulmonary circulatory troubles in hyperæmia of the lung, by checking venous stasis; (3) upon the size of the tumor, by contracting its walls and the tissues surrounding it. As a result of the diminution in size of the tumor, the pressure effects are relieved.

The Percussion Limits of the Stomach.

In a paper in the *St. Petersburger medicinische Wochenschrift* on the boundaries of the stomach and intestinal canal, by Dr. P. Jaschtschenko of Rostoff on the Don, the view of Traube and some other anatomists, that the stomach when empty falls back and does not lie in apposition with the abdominal or chest wall, is controverted; and so is his belief that the fuller the stomach is the lower its inferior border lies. According to Dr. Jaschtschenko's observations, the inferior border of the transverse colon extends as far downward as the umbilicus; the superior border, which is 2¼ inches higher, lies at a distance of 1½ inches below the sternum. When the gut is quite empty, the inferior border lies a little higher, or ⅓ inch above the umbilicus. In the right and left hypochondriac regions the superior border passes under the costal arch, being covered on the right side by the lower border of the thorax and the lower border of the liver, and on the left by the lower border of the thorax only. If the left half of the transverse colon and the upper part of the descending colon are full, the stomach being empty, a more or less dull percussion sound will be obtained over the lower part of the thorax on the left side, but above this there will be a tympanitic note up to the inferior border of the lung. If a part of the colon is empty, the stomach being full, a dull note will be obtained over the stomach, and a tympanitic note over the transverse and descending colon—that is, when the individual is in a standing or sitting posture. When he is lying on his back there will be a tympanitic note all over, with the exception of course of the region of the spleen. It is known that the superior border of the stomach lies against the lower border of the left lung, its inferior border coinciding with the transverse colon. This never changes its place, the filling of the stomach causing the dulness to extend from below upward, not from above downward, as Traube thought. Again, the stomach when empty does not collapse and fall back, for it is always under these circumstances distended with air. After death, in consequence of the loss of tone of the diaphragm, the abdominal organs rise somewhat above their position during life.—*Lancet,* August 18, 1888.

Temperature and Pulse During Menstruation.

In the Russian weekly *Vratch*, No. 35, 1888, Dr. Alexander V. Repreff, of St. Petersburg, writes that he has carefully examined the temperature and pulse before, during and after menstruation in 49 healthy and sick women, and that he has arrived at some important results of great interest both to the physiologist and to the practitioner. The outcome of Dr. Repreff's laborious observations (varying in duration from 11 to 42 days, with 4 measurements daily) may be briefly given as follows:

1. Healthy Women. There were 10 of these; 8 girls, from 15 to 27 years old; and 2 women, 41 and 23 years of age. Both the temperature and pulse during menstruation were found to fall below the average figures as observed in the same subject during the intermenstrual period. For a day, or several days immediately before and after menstruation, both the temperature and pulse manifest a rise above the intermenstrual average figures. This rise, however, never reaches a febrile height, which circumstance is said to be a characteristic feature of a normal condition of things. The said variations of the temperature are invariably strictly parallel with those of the pulse. The rectal varies with the axillary temperature, which constitutes another characteristic sign of the woman's local and general healthy state.

2. Sick Women. Of these there were 39. In women suffering with chronic uterine affections, the temperature and pulse during the catamenia rise above the individual normal level. In some cases, however, there are observed falls during the first and last day of the bleeding. In women suffering from oöphoritis and salpingitis, the temperature and pulse rise up to a febrile height immediately before and after, but oscillate about the normal level during menstruation. The rise is especially high in cases complicated with recent peritoneal inflammation. In women suffering with a mass of morbid processes simultaneously, the temperature and pulse present irregular oscillations. The parallelism between the thermic variations and those of the pulse is often absent in morbid cases. The same may be said in regard to the rectal and axillary temperature: sometimes, the axillary temperature and the pulse fall, while the rectal temperature rises. In a woman with amenorrhœa of three months' standing, there was observed, at regular intervals of four weeks, a rise of the pulse and the rectal and axillary temperature above the individual standard, which lasted on every occasion four days, and coincided with the appearance of lumbar pain, mucous discharge from the uterus and mucous diarrhœa.

3. The general conclusions are: 1. Menstrual variations of the temperature and pulse in healthy women are characterized by certain constant and typical features. 2. The latter disappear as soon as the woman falls ill. 3. Hence, under certain conditions, the menstrual temperature and pulse may serve as a diagnostic means for determining the state of the woman's sexual apparatus. The indications of the kind are especially valuable in cases of more or less latent sexual affections, such as a gonorrhœal disease of the internal sexual organs. 4. The behavior of the temperature and pulse in connection with menstruation gives an additional proof in favor of the view that the process is a general systemic one (and not local only), as Andrëëff, Rabutôt, Goodman, Mary Putnam-Jacobi, Stephenson, Carl Reinl, Hegar, etc., think and teach.

Vomiting of Pregnancy.

In connection with the case of a pregnant woman who suffered with uncontrollable vomiting, but who refused to have abortion induced, and died within twenty-five days, Jaffe, of Frankfort, makes some remarks upon hyperemesis gravidorum (*Volkmann's Sammlung klinischer Vorträge*, No. 305). He divides the vomiting of pregnancy into three classes. In the first, vomiting occurs only in the morning on an empty stomach; this is the most frequent form and the prognosis of it is good. In the second, which is not rare, vomiting occurs in the morning and also during the day after taking food, though only a part of the food is vomited. In this form the appetite is good, and the nutrition is not altered. With the occurrence of the movements of the fœtus the vomiting disappears. The third form, uncontrollable vomiting, is rare. It begins with the occurrence of conception, or first appears later. It is undecided whether it is more frequent in primiparæ or in multiparæ. The etiology is not known. If the affection is called a reflex neurosis, still this is only a definition that says nothing. The course of the disease exhibits three stages. In the first stage all nourishment is rejected; there is no fever, but thirst, pain in the epigastrium, salivation, and often constipation and anæmia, together with emaciation. In the second stage there is slight fever, the tongue is dry, and there is pain in the

epigastrium. The expired air is foul-smelling, the urine is concentrated and contains albumin and casts, which are the result of a nephritis produced by the inanition. The emaciation and the failure of strength increase. In the third stage high fever persists, delirium occurs, the patient sinks into a sleepy condition, and dies.

The diagnosis presents no difficulty. In the differential diagnosis diseases of the stomach and neuroses are to be considered. The prognosis is very uncertain; it is influenced both by the period in which the hyperemesis occurs, and by the life or death of the fœtus.

Treatment by diet and with medicines is generally ineffectual; the best agents are opium and the bromides. If local affections are present, a treatment directed to them is at times effective. If other measures fail, the pregnancy is to be interrupted—but not if the third stage has been entered upon, for in this case the patient is irretrievably lost.—*Wiener med. Presse*, September 9, 1888.

Action of Methylgreen in Checking Coagulation of the Blood.

In *Virchow's Archiv*, September, 1888, there is a paper by Professor A. Mosso, of Turin, on the employment of methylgreen for the recognition of the chemical reaction and of the death of cells. He finds that the methylgreen hinders coagulation of the blood. A solution of five-tenths per cent. methylgreen in a seventy-five hundredths per cent. salt solution retards coagulation of the blood considerably, even though only thirty minims of it are used to eleven fluid drachms of blood. If fifty or sixty minims of the solution just mentioned are added to eleven fluid drachms of blood, coagulation no longer occurs.

The leucocytes in blood that has been rendered uncoagulable by means of methylgreen are in their substance uncolored, while in their interior the so-called nuclei are stained emerald green. In some, the green substance is diffused throughout and fills the whole blood corpuscle; other leucocytes, on the contrary, are completely colorless, but the greatest part of the blood-corpuscles is violet, without a trace of so-called nuclei.

If eighty or ninety-five minims of a five-tenths per cent. solution of methylgreen are mixed with eleven fluid drachms of blood which has been drawn directly from the arteries, the methylgreen can easily be seen to be decomposed. Microscopic examination proves that the intensity of the coloration of the blood corpuscles and of the serum does not correspond with the quantity of methylgreen mixed with the blood, and that many leucocytes remain white. If acetic acid is now added to this blood, no matter in what proportion, and the blood is then diluted with water, the characteristic green color no longer persists. This shows that the disappearance of the green color can not be ascribed to the alkalinity of the blood. Prof. Mosso assumed that methylgreen in contact with blood is decolorized by an oxidation process; he then set to work to determine if the same phenomenon could not be brought about in some way by peroxide of hydrogen. The results obtained fully established his previous supposition.

The Fumes of Ether for Tinnitus Aurium.

In a paper read before the Cincinnati Academy of Medicine, September 10, 1888 (*Lancet-Clinic*, Sept. 29, 1888), Dr. J. E. Boylan reported a case of tinnitus aurium in which great improvement had followed the use of the fumes of sulphuric ether, which were insufflated through the Eustachian catheter. The patient was a man 40 years old, who had had chronic otorrhœa since he was a boy. After the first application of the ether very carefully carried out, the patient returned much elated; the noises, previously almost continuous, had ceased shortly after the application, and remained away for six or eight hours. After the second application they remained away for twelve hours, and when they returned they were of a much milder character. They continued to yield to the treatment, and the patient obtained a rest at night such as he had not known for a year. In order to satisfy himself that it really was the ether vapor that was benefiting the patient, Dr. Boylan substituted water upon two occasions; but this change was followed, in both instances, by a complaint that the noises had been severe and almost ceaseless. Upon another occasion, when the ether in the bottle used had become almost exhausted, the treatment had very little effect; but after replenishing the bottle, the good results were again immediately manifest. Dr. Boylan says he has now been treating the patient for over two months; his general condition is much improved; the noises, which are only discernible at intervals, are slight and of a totally different character (ringing). He pursues his vocation, which is that of a painter, and is very careful never to miss treatment.

Poisoning with Benzoate of Sodium.

In the *Centralblatt f. d. med. Wissenschaften*, July 21, 1888, Dr. K. A. H. Mörner, of Stockholm, communicates a case of poisoning with benzoate of sodium, which he thinks is the first hitherto reported. It seems that in the hospital of Sabbatsberg, at Stockholm, a patient was operated on for an ovarian cyst (dermoid), but the cyst could not be removed. Its contents, however, were evacuated and more than three ounces of benzoate of sodium, with some naphthaline, introduced into the sac. Some thirty hours after the operation symptoms of poisoning occurred. The patient sank into a condition of confused delirium, alternating with a sleepy condition; these symptoms passed away after a few hours. On the following day they returned in a milder form, and then staid away. The temperature during this time was 98.6° to 102.4° F. Perspiration did not occur in an important degree. There were no convulsions, but only trembling of the hands. The pulse was small, 120 to the minute.

As soon as the symptoms of poisoning appeared, the cyst was washed out with water. The urine which the patient passed after the first appearance of the poisoning was sent to Dr. Mörner for examination. The latter describes it as moderately dark, reddish-brown, and becoming somewhat darker. It showed a slight green fluorescence. The reaction was strongly acid; the specific gravity 1026; albumin and peptone were not present. It reduced an alkaline solution of oxide of copper and oxide of bismuth; but owing to the small quantity of urine it was not determined whether or not this reduction was due to the presence of sugar. The color of the urine was not due, as was at first supposed, to the naphthaline that had been used, but to the presence of a large amount of urobiline. Naphthaline was also excluded as the cause of the poisoning. On the contrary, the belief that benzoate of sodium was the cause of the poisoning seems to be completely justified, for the urine contained very decided quantities of hippuric acid, which upon the addition of hydrochloric acid crystallized out in such quantities that the fluid was almost filled with the needle-like crystals. Two quantitative estimations of the hippuric acid (one according to the method of Bunge and Schmiedeberg, the other according to that of Meissner) gave 28.68 grains and 29.43 grains respectively in about three ounces and a quarter of urine. In the refining of the hippuric acid with rhigolene only a little was extracted—1¼ grains. The rhigolene solution left behind a resinous residue, from which Mörner did not succeed in obtaining crystals of benzoic acid.

In spite of the large quantity of benzoic acid absorbed no unchanged benzoic acid was excreted. Meissner having declared that benzoic acid may be changed in the organism into succinic acid, the urine was investigated for the latter, but with negative result. The amount of nitrogen in the urine was pretty high—9 grains in about 3 ounces, which, after subtraction of about 2½ grains belonging to the hippuric acid, makes the nitrogen correspond with 46½ grains of urea in about 3 ounces of urine; it seems to him not improbable that the excretion of urea was increased, as Salkowski had found to be the case in the dog after the administration of large quantities of benzoic acid.

Dr. Mörner says that in a small portion of urine which was passed two days later he could not find any hippuric acid.

Removal of Tattoo-Marks.

The removal of tattoo-marks has always been considered a very difficult feat. Many methods have been recommended at various times, a pretty sure sign that none of them is very satisfactory. Dr. G. Variot, of the Paris Biological Society, has recently proposed a new process, which he declares to be invariably successful in removing blue and red tattoo-marks. Without hazarding an opinion beforehand, one must admit that the method is based on apparently sound principles. But it is, perhaps, well here to remark that Dr. Variot is attached to the central infirmary of the Paris prisons, and therefore in excellent position to experiment with such disfigurements, since, for some inscrutable reason, criminals, who have most to fear from identification, are just the men who most often brand their persons with indelible marks. Dr. Variot operates as follows: The tattooed parts are first wet with a concentrated solution of tannin, and with a set of tattooing-needles the skin is punctured all over the colored portions to the depth usually adopted by professionals. All the parts tattooed with tannin are next rubbed over with the lunar-caustic pencil, the silver salt being allowed to act upon the epidermis and derma until the needle-pricks have turned a deep black. The excess of liquid being now wiped off, things are allowed to follow their natural course. The whole surface treated will soon turn black. The pain, quite moderate during the operation, continues to be slight for the first two

days, and is accompanied with some local inflammation. After the third or fourth day no more pain is felt, and, except for large marks, no dressing will be necessary. After fourteen or eighteen days the eschar will fall off and leave, instead of the tattoo-marks, a reddish superficial cicatrix, which will gradually turn paler, and, after two months, almost disappear. On close scrutiny it will probably remain always perceptible, but it will otherwise be scarcely noticeable, and, at all events, the skin will show no trace of the former emblems, more or less artistic. In explanation of the remedy's mode of action, Dr. Variot thinks that the coloring-matter forming the tattoo-marks is generally localized in the upper third of the derma, the deeper portions remaining unaffected. On tattooing at first with tannin, the solution penetrates exactly to the same depth as the foreign particles, and, acting as a mordant for the silver nitrate, enables the caustic solution to permeate the derma to the proper depth and no further. Hence the skin will preserve its elasticity, and the scar be so little apparent. Before finding out the foregoing process, others were unsuccessfully tried on prisoners, at their request, and it may not be useless here to briefly point out their imperfections. Blisters, even kept up some time, proved entirely insufficient. They do not reach deep enough. Red-hot iron was found unmanageable and dangerous, too short an application being useless, and too long a one leaving painful sores and ugly scars. As to tattooing with a number of blistering or caustic solutions, including silver nitrate, they were scarcely satisfactory, although coming nearer the mark. Their main fault was that they were exceedingly painful, even when the punctures were not deep enough. But when tannin was first applied, and then lunar caustic, the results were all that could be desired.—*Therapeutic Gazette*, September, 1888.

Lead Poisoning in Domestic Animals.

The Paris correspondent of the *Therapeutic Gazette*, September, 1888, says that the effects of chronic lead-poisoning on man are well enough known, but the way domestic animals are affected under the same circumstances is not so well known. And yet a better knowledge of the symptoms would often be of some usefulness, as it would supply a clue to the cause of obscure epidemic poisonings. An interesting contribution to this branch of toxicology has been incidentally supplied by Dr. Cornillon, one of the physicians and chemists delegated to investigate the poisoning cases which not long since occurred at Gannat, near Vichy. The lead was introduced into flour through the ignorance of a workman, who had plugged with white lead a defective millstone in a mill which used to grind all the village corn. Of course the plumbic carbonate dropped off, got mixed with the flour, and poisoned nearly every one around. Among human patients the symptoms were, with a few exceptions, the customary ones. But domestic animals, fed with the same bread, afforded very curious symptoms. In some families the dogs became so restless and barked in so fearful a manner and so ceaselessly that their masters, thinking them mad, had them killed. Chickens simply died; hens bore the poison better, but stopped laying eggs. In one farm, after all the family had been sick, they had quite a quantity of the poisonous flour left, and tried to feed it to pigs. But three of the animals, which were sold soon after, died at the buyer's, and the three others first refused to eat for several days, and finally died. Their gums had the characteristic blue tinge, and obstinate constipation was observed, indicating saturnine paralysis. Another particularity worthy of remark was that, while hens ceased to lay, menstruation troubles among the Gannat women were unusually prevalent.

Extract of Pancreas in Atrophic Catarrh of the Stomach.

Dr. Reichmann, of Warscham, at the meeting of the Congress of Polish Physicians and Naturalists, July 18–22, 1888, said that atrophic catarrh of the stomach, so called because of the atrophy of the glands of the stomach and consequent lack of gastric juice which are present, was a very disagreeable form of disease of the stomach for the physician to treat. Glands that have become changed anatomically cannot be regenerated. Dr. Reichmann has observed the disease ten times in one hundred and seven patients with disease of the stomach. As neither hydrochloric acid, nor pepsin, nor other agents introduced from the outside were of assistance, Dr. Reichmann tried alcoholic extract of pancreas (12 to 15 per cent.) and pancreatine, and was convinced that digestion of the food, which before remained stagnant and coarse, was rapid and complete. The symptoms of the disease changed quickly, and the general condition of the patient improved in a pretty short time. —*Wiener med. Presse*, September 9, 1888.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE PERILS OF THE PHYSICIAN'S LIFE.

Among the usual vicissitudes of the physician's life are fatigue, anxiety, and exposure to disease; weariness of body and severe mental strain; and at times distrust, ingratitude, or even calumny. Besides this, on occasions which are fortunately rare, the physician is exposed to the brutal rage of jealous or unreasoning men, and his errands of mercy may lead him into great physical danger or even to death.

An illustration of the extremest outcome of the faithful discharge of the physician's duty has recently been reported from Georgia, where, on October 21, 1888, Dr. J. B. Manson, one of the most eminent, skillful and benevolent physicians of that State, lost his life as the result of a brutal assault made upon him by the father of a child he was treating for typhoid fever. No reason is assigned for this inhuman act, except that the perpetrator of it may have been insane. Be this as it may, he fell upon the benefactor of his child with the fury of a madman, and, with violently abusive language, beat him so cruelly that he died within three days.

This occurrence exceeds in horror anything which we can now recall among the unfortunate experiences of medical men. It surpasses in barbarity even those instances —of which there are not a few—in which physicians have been decoyed from their homes with a tale of suffering, in order that they might be waylaid and robbed; and it brings forcibly to mind the perils of a calling which often calls for a degree of courage and devotion which our fellow-men sometimes seem to forget.

Fortunately, as we have said, such extreme instances as this are of rare occurrence; but unfortunately instances of lesser danger are not uncommon. There is probably no medical man of much experience who could not narrate stories of imminent peril to his life, incurred solely because he followed the path of duty without flinching from its risks; of the dangerous rise of passion in the hearts of men inflamed by suspicion or brutalized with drink; of scenes of violence or of crime to which his professional duties led his feet; of outcasts or desperadoes to whom he had ministered at his own peril. In addition to this, who among us has not again and again risked his life in the care of persons suffering with contagious diseases, while those whose bereavement he was endeavoring to avert watched him with distrust and repaid him with ingratitude?

These are the hardships of the physician's lot—these and the labor and anxieties which

go with them. In looking at this side of his experience, one sometimes wonders that so many men are found, day by day pursuing their ministry of mercy, unquailing, uncomplaining, and asking no special recognition of their heroism. Into the haunts of vice of great cities, and the lairs of desperadoes on the edges of civilization, they go; into rooms reeking with infection and towns where epidemics rage; and ever they bear with them a spirit of self-sacrifice which has few parallels in mortal experience. Such, we rejoice to know, are the men who by thousands cover every civilized land with their ministry of mercy, and make up the grand army of healers.

Once in a long while—as now—some startling occurrence attracts the attention of the community to the character of their work; and then, for a little, they may find some appreciation of its hardships, and a cessation of the carping criticism to which they are often subjected. In the main, however, they cannot look for any such consideration to support them in the discharge of their duty, but rather to the principles of fidelity and humanity which are their surest and most constant reliance. "*Fortiter, fidelite*" is their motto; and "*feliciter*" is their reward when only it can be attained.

INHALATION OF CARBONIC ACID IN DYSPNŒA.

It certainly seems like "setting a thief to catch a thief" when we find it recommended to give inhalations of carbonic acid to relieve dyspnœa, and yet at a meeting of the Academy of Sciences in Paris on February 27, 1888, Dr. Edmond Weill spoke very highly of this very procedure. In a number of cases of laryngitis and advanced phthisis he had administered by inhalation from two to four quarts of carbonic acid gas, once or twice a day. The effect was to cut short paroxysms of dyspnœa, if the inhalation took place when a paroxysm was in progress; and if it was made between the attacks the respiration became much more free, and the paroxysms became less frequent, shorter and less severe. The same results were observed after inhalations of carbonic acid gas in attacks of dyspnœa in emphysema with albuminuria. Dr. Weill compares the effect of these inhalations with that of hypodermic injections of morphia.

This curious therapeutic method seems so contrary to all preconceived notions of the physiology of respiration that it would require some courage to adopt it. But it is well known that morphia will often do more good by diminishing reflex irritation, than harm by obtunding the respiratory centres; and it is by no means unreasonable to suppose that carbonic acid gas may do more good as an anæsthetic than it will do harm as a poison. It would be interesting and instructive to have some confirmation or correction on this side of the Atlantic of Dr. Weill's views in regard to the value of inhalations of this gas in dyspnœa; for if it can accomplish here what he has claimed for it, it may be a very valuable addition to our therapeutic armamentarium.

TREATMENT OF RETROFLEXION AND PROLAPSE OF THE UTERUS.

At the last meeting of the Association of German Naturalists and Physicians, Dr. Adrian Tchücking, of Pyrmont, read an interesting paper which is published in the *Deutsche med. Wochenschrift*, October 4, 1888, and in which he described and advocated a novel method of correcting retroflexion and prolapse of the uterus. His method consists in drawing the uterus forcibly downward, and passing a ligature through its cavity and substance and then through the vaginal wall, so as to fix the womb in a position of extreme anteversion.

To do this requires a needle and holder of peculiar construction, a certain dexterity, and the observance of careful aseptic precautions. The result has been very satisfactory in the twelve cases in which he had,

at the time he read his paper, carried out his method. The uterus, soon after he removed the ligature, assumed a perfectly normal position, and the troubles dependent upon its former malposition disappeared in most of the cases.

Dr. Tchücking's description of the method is not quite as full and complete as we might wish, and he does not describe the instrument he uses at all. But, so far as his paper goes, it seems to indicate that his method is not difficult of execution, that it is quite free from danger, and that it accomplishes excellent results. Under these circumstances it certainly deserves the attention of gynecologists, and we hope it may prove a useful addition to our resources for the treatment of conditions which are a cause of much suffering to women, and which often tax severely the skill and ingenuity of their medical attendants.

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

At the time when the first Congress of American Physicians and Surgeons was meeting at Washington, the first gathering was held of a society to be called the American Association of Obstetricians and Gynecologists. This organization is intended to give greater prominence to the study of obstetrics than it has had in any of the existing national societies, and to blend the study with that of gynecology. The proceedings at the first annual meeting were very interesting. There was rather too great a preponderance of gynecological subjects on the programme; but the papers were excellent and the discussions were very instructive.

The idea of having an Association largely devoted to Obstetrics is a good one, and we hope this one may prove a valuable addition to the number of national associations which have of late years done so much to advance the science and art of medicine in the United States.

THE PHYSICIAN'S POCKET RECORD.

Last year we announced the preparation of a new and thoroughly revised edition of the POCKET RECORD published at this office, which has so long been a favorite with the Profession.

Inexperience in this work, however, led to our being disappointed by the printer, and when the Pocket Record came out, it had been delayed so long that many of our subscribers had to turn to other sources.

This year we have made better arrangements, and we shall have a new edition ready in good time. We therefore beg our readers to send in their orders now (without money) for Pocket Records for 1889. As soon as the books are ready, we will notify those whose orders we have received, and they may remit payment then.

The price will be: One Dollar for a Pocket Record for thirty patients a week and $1.25 for a Pocket Record for sixty patients a week.

The books for 1889 will be printed *with dates*. Orders for books without dates (perpetual) will be taken; but we think most medical men prefer the dates printed in the book.

We have on hand some of the last edition of books without dates and will sell them for fifty cents each, if the money is sent with the order.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

A TEXT-BOOK OF HUMAN PHYSIOLOGY. By AUSTIN FLINT, M.D., LL.D., Professor of Physiology and Physiological Anatomy in the Bellevue Hospital Medical College, New York, etc. With three hundred and sixteen figures in the text and two plates. Fourth edition, entirely rewritten. Large 8vo, pp. xvii, 872. New York: D. Appleton & Company, 1888. Price, cloth, $6.00.

It is not necessary to say much in announcing the appearance of the fourth edition of this magnificent work, which has already taken rank as one of the most learned and most practical treatises on physiology in the English, or any other, language. The present edition includes the most recent advances in the science of physiology, and in remodelling and rewriting the work the author has used excellent

discrimination as to what should be omitted, what retained, and what added to the contents of the earlier editions. We are glad to note also that his book is not filled with pictures of complicated and multiplied apparatus, and that the illustrations found in its pages are instructive and useful. It need hardly be added that they are beautifully executed.

There is so much which might be said in praise of this book that we have little inclination to criticise it; but we would have been glad if the author had included in it a chapter on teratology, although this may have been omitted on the ground that it belongs rather to pathology than to physiology. Again, it would be interesting to find some reference to the very curious assertions in regard to fecundation after castration of the male, such as we laid before the readers of the REPORTER, in an Editorial in the issue for May 19, 1888.

Other matters which they would like to see discussed will doubtless occur to those who study Dr. Flint's book carefully; but, on the whole, it is remarkably complete, and will not disappoint any reasonable expectation. Its literary and scientific value is very great, and its mechanical execution is equal to the best that comes from the excellent publishing house which has issued it.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS AND MATERIA MEDICA. By T. LAUDER BRUNTON, M D., D.Sc., F.R S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital, etc. Adapted to the United States Pharmacopœa (*sic*) by Francis H. Williams, M.D., Boston, Mass. Third edition. 8vo, pp. 1, 1261. Philadelphia: Lea Brothers & Co., 1888. Price, cloth, $5.50; sheep, $6.50.

This book has already been long enough before the medical profession to require little more than the announcement of the appearance of a new edition to attract the attention of our readers. The present edition has the same merits of fulness and clearness which its predecessors possessed, and bears the same impress of the individuality of the author. It has been revised so as to devote more attention to certain subjects which have undergone rapid development during the last few years, although it has not caught up with the most recent data in regard to such drugs as antipyrine, used as a nervine; calomel used as a diuretic; sulphonal; etc. So much could not, of course, be expected of a book requiring so much time for its printing as this one has required; and with extremely few exceptions, we believe it presents a very accurate view of the present state of knowledge in regard to its subject. A noticeable feature of this book is its very complete index of remedies, and a helpful index of diseases and the medicaments which may be used in the treatment of them.

LITERARY NOTES.

The first number of the *Maritime Medical News*, a bi-monthly journal, published at Halifax, Nova Scotia, has just appeared. It contains twenty-six pages of reading matter and six pages of advertising. Its size is 11¼ x 8¼ inches. The subscription price is $1.00 a year. Its contents are interesting and well edited, and it gives promise of usefulness. We share the conviction of the editors that there is room for a journal published with special reference to the professional interests of the Maritime Provinces of British America, and heartily wish this one success.

NOTES AND COMMENTS.

Carbonic Acid Water as a Vehicle for Creasote.

The taste and odor of creasote are so disagreeable to many patients that physicians have in some instances been deterred from prescribing it, especially in the large doses in which it has been advised by German writers. It is true, when given in capsules the taste and odor are not perceived; but this form of administration is objectionable when large doses are given, because the drug then reaches the stomach in a concentrated form. In the *Berliner klin. Wochenschrift*, August 6 and 13, 1888, Dr. J. Rosenthal advises the use of carbonic acid water containing cognac as a vehicle for the creasote. This combination, he says, is comparatively tasteless and obviates the disadvantages attending the administration of creasote in a concentrated form. The mixture is put up in bottles holding five and a half, ten and a half, and sixteen ounces. The smallest bottles contain from one and a half to three minims of creasote and seventy-five minims of cognac; the middle-sized bottles, six minims of creasote and two and a half fluid drachms of cognac; while the largest contain nine minims of creasote and three and a half fluid drachms of cognac. During the first week the patient is directed to take one of the smallest bottles after dinner and supper each day; during the second week he should take a half bottle of the next stronger water after breakfast and dinner, but continue to take the weaker water after supper. The quantity of creasote which he takes may in this way be increased gradually until the maximum dose of twelve and a half minims a day is reached.

Antipyretic Action of Phenacetine.

Dr. Armin Huber reports, in the *Correspondenz-Blatt für Schweizer Aerzte*, No. 18, the experience with phenacetine as an antipyretic, gathered from Prof. Eichhorst's clinic in Zurich. Phenacetine is without odor and taste, and as it is insoluble in most diluents, it was administered shaken up in some water or wine. In by far the greatest number of cases it was given in doses of fifteen grains, and only once a day. Apyrexia began in a few hours, with profuse perspiration. If the drug was given in the later hours of the forenoon, the period free of fever amounted to from five to seven hours and over. Phthisical patients remained

without exception free from fever the whole day. The increase of fever as a rule occurs slowly. The pulse often does not diminish in frequency with the fever, but remains high, though its tension is markedly increased. Collapse was never observed. The patients have no disagreeable feelings as the result of the action of the drug. Vomiting never occurred. In a few cases there was no exaltation of the subjective sensations. Huber calls attention especially to the fact that phenacetine acts as an antipyretic in all febrile diseases—in tuberculosis, typhus fever, polyarthritis, peritonitis, ulcerative endocarditis and fibrinous pneumonia. In a girl seventeen years old, with pneumonia of an upper lobe in the stage of hepatization, the temperature was brought down to normal from 102°.3 with fifteen grains of phenacetine. In a girl eighteen years old, suffering with polyarthritis, antipyrine was given in clysters to the amount of sixty grains a day for two days; the temperature on the first day fell about a degree. On the second day of taking the antipyrine, the temperature before taking it was 103°, after taking it 102°.3, and it soon again rose to 103°. Phenacetine was then given (fifteen grains) and on the first day the patient was free from fever for four hours. On the third day, when she took two doses of about sixty grains, she was without fever the whole day.

Huber considers that phenacetine is an antipyretic preferable to antipyrine.—*Wiener med. Presse*, October 21, 1888.

Causes Determining the Creation of the Sexes.

Charpentier says it seems that the absolute or relative age of the parents has a certain influence upon the production of the sex of the embryo, and so have both the more or less pronounced degree of sexual vigor of the father, and the moment at which the egg has been fecundated after its expulsion from the ovary. It seems to be established with sufficient clearness that, when the man is ten years older than the woman, while she is at the period of highest sexual activity, more boys than girls are born. Moreover, the fecundating element which is most energetic from a sexual point of view, possesses the property of engendering more individuals of its own sex. Finally, when coitus is practised slowly after menstruation (eight days at least), the production of boys is favored. The general proportion is 106 boys to 100 girls.

Bidder, whose researches have been based upon a total of 11,871 confinements, arrives at the following conclusions:

1. Very young primiparæ beget more boys. 2. Primiparæ in middle life, that is to say, at the time of full generative vigor, beget more girls. 3. After this latter period has been passed, they beget more boys. 4. The results are the same in multiparæ, but the age at which the diminution of the number of boys appears occurs a little later.

It would seem, according to Bidder, that the sex of the child holds to the male or female quality of the ovule. Male ovules will be more numerous and more likely to be fertilized in early and in advanced age. On the contrary, during the period of full generative vigor of the woman, female ovules are more numerous and more likely to be fertilized.—*Bulletin Médical*, Oct. 17, 1888.

Johns Hopkins University.

In an article in the *Independent*, Oct. 25, 1888, President Gilman says, among other things, that Mr. Hopkins left a large sum to found a hospital, with the intention that the university should establish a medical school in connection therewith. The hospital buildings are now completed, and the university has already established three professorships as the beginning of a medical department. "The only cause for anxiety in the future of the Johns Hopkins University," says President Gilman, "is the suspension of dividends by the Baltimore and Ohio Railroad. The founder gave the university fifteen thousand shares of the common stock of the railroad, and he recommended the trustees in the most explicit terms to keep, protect, and defend this investment." The income from this stock has been about $150,000 a year, and has been the main support of the university; and, now that it has ceased for a time, there is little to sustain the institution except the tuition-fees and the moderate surplus that has been accumulated in past years. President Gilman suggests that the friends of the university should make up an emergency fund to relieve its present needs, and expresses confidence that such an institution as the Johns Hopkins University "will not long be allowed to suffer for the want of an income." This confidence we believe to be justified; and certainly every lover of learning will hope that a university of so much promise may suffer no check in its useful career.—*Science*, Nov. 2, 1888.

Do Library Books Spread Infection?

A good deal of discussion having taken place on the subject of the spread of infectious diseases by means of the books in circulating libraries, the Dresden municipal authorities have had a thorough experimental investigation of this question conducted. A number of much-used volumes from the town library were taken for the purpose. The dust from the leaves and covers was sown in nutrient media and cultures reared, the result being that no microbes belonging to infectious diseases were found—the dust being, in fact, nothing but ordinary dust of a harmless character. Again, the dirtiest leaves in the books were rubbed first with the dry finger and then with the wet finger. In the first case scarcely any microbes were found on the finger; in the second case plenty were found, but all appeared to be of a non-infectious character. Especially is it noted that there were no tubercle bacilli. Lastly, books were soaked for two days in spirit containing 10 per cent. of carbolic acid. This treatment destroyed all the bacilli, and proved harmless to the volumes. The conclusion arrived at was that the danger of circulating libraries spreading infection is very slight; but a recommendation is given to dust books well before reading them, and never to wet the finger in the mouth for the purpose of turning over the leaves.—*Lancet*, Aug. 18, 1888.

Traumatic Subdural Abscess of the Brain.

Sir William Stokes, Professor of Surgery in the Royal College of Surgeons, Ireland, concludes a paper in the *Dublin Journal of Medical Science*, October, 1888, with the following deductions.

1. That after the primary symptoms of cerebral traumatism have subsided, there is frequently a latent period of varying length, during which there are no distinct brain symptoms whatever connected with abscess formations.

2. That their appearance is, as a rule, sudden, and if uninterfered with they run a rapidly fatal course.

3. That the occurrence of pus production resulting from cerebral traumatisms is not incompatible with a perfectly apyrexial condition.

4. That this latter fact will probably aid in differentiating traumatic cerebral abscess from meningeal or encephalic inflammation.

5. That both as regards color and consistence there is great variety in the contents of cerebral abscess cavities, and that, as shown in Wilm's case, published by Rose, of Berlin, they may become transparent.

6. That antisepticism has largely diminished the risks of the operation of trephining.

7. That, having regard to the great mortality of cases of cerebral abscess when uninterfered with—viz., from 90 to 100 per cent.—the operation is indicated even when the patient is *in extremis*.

8. That, in the case when the trephine opening does not correspond to the situation of the abscess, exploratory puncture and aspiration may be employed.

9. That by the adoption of this measure the necessity for multiple trephine openings can be largely obviated.

10. That the employment of a blunt-pointed aspirating needle, as suggested by Rentz, is probably the safest mode of exploration and evacuation.

11. That drainage is desirable in the after-treatment of such cases.

12. That both during and subsequent to operative interference in these cases a rigid antisepticism is imperatively required.

Valves in the Veins of the Human Intestines.

Dr. W. S. Bryant's conclusions are: "These observations show that at birth the valves in the intestines are quite numerous in man, and at this age they are more abundant in the large intestine. Also that in a few months the valves either disappear or become incompetent, with few exceptions. In adult men there are usually a few valves, and these are more abundant in the small intestine, especially in the superficial tributaries of the venæ breves. These valves are more numerous in the jejunum, and disappear as we approach the cæcum.

"Though the valves just described were discovered since Hochstetter's paper was written, his remarks on the significance of valves in the portal system will apply to them. After alluding to the fact that the presence of valves in the branches of the portal vein seems widely spread among mammals, he says: 'But only in individual species, as in the beasts of prey, do the valves possess great importance in connection with the circulation. In many species they are to be considered much more as rudimentary organs, which act either only in youth, as in men and perhaps the ape, and later in part or wholly disappear; or for the most part, as in the rabbit, are very imperfect.'"—*Boston Med. and Surg. Journal*, Oct. 25, 1888.

Decree Concerning Foreigners in France.

This decree, which has now been signed by the Minister of the Interior and the President of the Republic, and has already come into execution, contains some points of interest. It is required that every foreigner not domiciled in France, but who intends to make his residence in the country, shall, within fifteen days after his arrival, make the following declaration to the mayor of the place in which he wishes to reside. 1. His name, surname, and those of his father and mother. 2. His nationality. 3. Date and place of birth. 4. Place of former residence. 5. Means of existence. 6. Name, age, and nationality of his wife and children, if any. Documents must be shown to support his declaration. The declarations must be made, as far as Paris is concerned, to the Prefect of Police. Strangers at present residing in France, and not having a fixed residence (*non admis à domicile*), will be allowed a delay of one month to enable them to comply with the foregoing requirement. Infringements against these formalities will be punished by ordinary police penalties, without prejudice to the right of expulsion possessed by the Minister of the Interior.—*Medical Press and Circular*, Oct. 10, 1888.

Statistics of the Population of France.

The *Journal Officiel* has just issued the report on the population of France for last year, which will be found more or less interesting. 278,056 marriages, 899,333 births, and 842,797 deaths took place during the period, showing an increase in the population of 56,536 individuals, or 3,920 more than during the preceding year. In spite of the increase, however slight, it is noteworthy that there is a steady decrease (12,808 annually) in the births during the last seven years. Of the total number of births registered during the year, 73,854 were illegitimate, giving a proportion of over 8 per cent. of the whole. In the department of the Seine (Paris) the percentage reached the high figure of 25, while in that of Finisterre it sank to 2. With reference to the fecundity of marriages the result is deplorable. A hundred women under fifty years of age furnished to the population only sixteen children, that is to say, one birth takes place in every six households. The proportion of boys to girls is as 105 to 100, but the advantage is lost in the deaths, as more men than women die in the year (107 to 100). The average number of deaths per 1,000 for 1887 was 22.—*Medical Press and Circular*, October 10, 1888.

The Limits of Hearing.

In the *Glasgow Medical Journal*, August and September, 1888, Dr. J. Kerr Love communicates an elaborate inquiry into the limits of hearing. A summary of his paper is as follows:

1. Notes produced by 15 or 16 vibrations per second are the lowest which can be heard by the human ear. The difficulty of producing vibrations of sufficient amplitude to make such notes heard is great, but it is probable that sounds caused by a smaller number of vibrations are perceived as separate impulses and not as true musical sounds. Many ears cannot hear notes caused by less than 24 vibrations.

2. The most powerful very high notes are produced by very small tuning-forks, and by them a vibration number of over 40,000 has been heard by Dr. Preyer and a few other observers. Other and more convenient means for producing very high notes are Mr. Galton's whistle and the small open pipes which the author has described in this paper. These tests show that most ears can hear nothing when the vibration frequency is over 30,000 per second. Many are deaf to notes produced by more than 20,000, and some to notes of 15,000 vibrations; in a few cases deafness to notes of 5,200 or 5,500 vibrations has been recorded.

3. The least observable difference in pitch is for untrained or slightly trained ears difficult to state, but (exclusive of cases of tone-deafness) it may be put down as from 1-6 to 1-40 semitone. The ears of such trained musicians as violinists, tuners, and some pianists, can perceive with certainty a difference of 1-64 to 1-80 semitone. All observers, but especially the untrained, detect sharpened better than flattened intervals. Generally speaking, Weber's Law holds good for all but the highest and lowest parts of the musical scale.

4. No quite satisfactory test has yet been found for the distance at which a sound of constant intensity can be heard. Politzer's Acoumeter is the best and most convenient test, and is heard by normal ears in almost perfect stillness at a distance of 49½ or 52½ feet.

5. Cases of tone or note deafness (deafness to intervals of a whole tone or more) are very rare, but some well-authenticated instances have been recorded.

Syphilis and Diabetes.

An interesting case is recorded in the June number of the *Annales de Dermatologie*, by Le Monnier, of Flers, of a patient 50 years old, who for five months had been suffering with diabetes, and passing sugar in his urine to the extent of 2 to 2½ ounces per quart. His condition was becoming serious, and the symptoms were increasing in severity, when suddenly he developed a gumma of his pharynx, which subsequently ulcerated, proving the presence of a syphilitic taint of which the patient had previously denied all knowledge. From the time that the gumma was discovered the patient was treated with iodide of potassium. At the end of eight days there was great improvement in the local affection, and, remarkably enough, the amount of sugar in the urine had fallen to 405 grains per quart. The treatment was continued, and, after the lapse of three months, the ulceration of the pharynx had cicatrized and all trace of sugar in the urine had vanished. The author remarks that, although the occurrence of syphilitic diabetes has not been disputed by Fournier, Lécorché, and others, still the case is worthy of publication owing to the fact that the usual diabetic treatment yielded no definite relief, and that the complications and progress of the disease were immediately arrested as soon as antisyphilitic remedies had been administered, resulting in the cure of the patient.—*Medical Press and Circular*, Oct. 10, 1888.

Vegetable Cows.

Several natural orders of the vegetable kingdom include plants that are characterized by the secretion of a fluid closely resembling milk in appearance and consistency, and a familiar example of these is to be seen in our common milkweed (*Asclepias cornuti*), which is well known to everybody. In some plants this milky fluid is of the most venomous nature; in others it possesses active medicinal virtues; in others it yields a product (such as india-rubber and gutta-percha) of the highest importance to the arts and industries; and in others still it proves of value as a human aliment. Since the same general properties characterize the plants of each natural family it seems an anomaly that, in the same order, we should find the species of one genus producing a lactescent fluid of a highly poisonous nature, and those of another yielding one that is entirely innocuous. Yet such is often the case, and we have a striking example of it in the bread-fruit order, the *Artocarpaceæ*, which, on the one hand, includes the celebrated upas tree of Java, which, when pierced, exudes a milky juice containing an acrid virulent poison (antiarin), the smallest quantity of which will kill the largest animal; and, on the other, the famous *Brosimum utili* of South America, which yields a copious supply of rich, wholesome milk, of as good a quality as that from the cow. There are several other instances in the vegetable kingdom of such an association, in the same natural order, of plants that produce a noxious lactescent juice with others which yield a wholesome one adapted for man's use, and which may therefore be designated as "vegetable cows." To speak only of the latter class, the most remarkable example is the species of *Brosimum* just mentioned, which was discovered and made known by the celebrated traveler Humboldt. This tree forms extensive forests on the mountains near the town of Coriaco and elsewhere along the sea-coast of Venezuela, growing to upward of one hundred feet in height, with a trunk six or eight feet in diameter, and branchless for the first sixty or seventy feet of its height. It is popularly known as the cow-tree, *palo de vaca* or *arbol de leche*. Its milk, which is obtained by making incisions in the trunk, so closely resembles the milk of the cow, both in appearance and quality, that it is commonly used as an article of food by the inhabitants of the places where the tree is abundant. Unlike many other vegetable milks, it is perfectly wholesome and very nourishing.—*Scientific American*.

New Treatment for Dislocation of the Jaw.

In *L'Union Médicale* is an account of a sportsman, who, in calling to his dog, dislocated his jaw. With great difficulty he made his way to the nearest town, arriving late at night, and rang the bell of the first physician he could find. The doctor put his head out of the window and asked who was there. But the sufferer was unable to utter a word, and dismayed at the closing of the window, rang again, still more vigorously. The same scene was reënacted several times, until the doctor, thinking it a practical joke, stole downstairs, and opening the door suddenly, struck the patient full in the face and slammed the door. As soon as the patient recovered from his astonishment he found his jaw entirely in place, and calling out "thank you," he went on his way rejoicing.—*Northwestern Lancet*, Oct. 15, 1888.

Case of Delusional Insanity.

"Some months ago," says the *Sacramento Medical Times*, October, 1888, "a wealthy rancher of this county conducted himself in such a manner that his family became apprehensive for their safety, and decided to confine him in an asylum. His resentment was principally directed against his wife, a woman of excellent character, advanced in years, the mother of a large family, whom he accused of having had intercourse with some of the farm hands. He stated that on several occasions he was on the same bed on which these acts were perpetrated, but in a cataleptic condition, the result of chloroform which she had administered. The method of administration was interesting. She had placed a handkerchief, saturated with chloroform, in the pocket of a dress which hung four feet from the head of his bed. On these facts and much additional evidence, three physicians decided that he was a monomaniac and that it was unsafe for him to be at large. A jury was impaneled, and in the face of the medical testimony and overwhelming evidence furnished by the accused and his family, they acquitted him of the charge. The result was mainly due to the efforts of able counsel for the defense. The accused had numerous friends who firmly believed in his sanity, and regarding him as the victim of designing people, helped him with testimony and funds. One man in particular was earnest in his protests against the outrage sought to be perpetrated upon his friend. Several months after the trial he asked the victim to witness a will of which he was the executor; this was duly done. Subsequently the testator died and the will was contested, when the same man testified upon oath that he never signed or saw the will, denied his own signature, and positively accused his friend, the executor, of sequestrating $1000 of the funds involved. Many similar cases have, no doubt, occurred, and it is most desirable that they should be recorded as furnishing important evidence on the intricate subject of mental jurisprudence."

—Professor Sachs, of Würzburg, has been invited to the Chair of Botany in the University of Munich, lately occupied by Professor Nägeli.

—Professor Unverricht, of Jena, has been offered the Chair of Medicine in the University of Dorpat, made vacant by the resignation of Professor Schultze, who went to Bonn.

NEWS.

—Dr. Harrison Allen has moved to 1933 Chestnut St., Philadelphia.

—Dr. Robert R. Livingston died in Plattsmouth, Neb., Sept. 28, 1888.

—Dr. Galippe, a French dentist, declares that antipyrine blackens the teeth, especially when they have lost their enamel.

—Dr. Joseph O'Dwyer has been appointed Professor of Diseases of Children in the New York Post-graduate School and Hospital.

—The remains of Dr. Jacob Vreeland, formerly of Brooklyn, N. Y., were brought to New York City from England, October 2. Dr. Vreeland went abroad on a vacation last August, but died September 2, of pneumonia. He was 60 years of age.

—Dr. John B. Hamilton has been appointed Editor of the *Journal of the American Medical Association*, and it is said that he intends to resign his position as Supervising Surgeon-General of the Marine Hospital Service, in order to accept the appointment.

—Thirty-three new cases of yellow fever and five deaths were reported in Jacksonville, Fla., Nov. 10, 1888. The weather is said to be cool, but there has been no frost. New cases are also reported from Gainesville and Fernandina, Fla., and from Decatur, Alabama.

—The committee in charge of the annual banquet of the Ex-Resident Physicians of the Philadelphia Hospital, Blockley, announces that the banquet will be held December 4. The time and place have not yet been announced. The committee is very desirous of having the names and addresses of all Ex-Resident Physicians, and will be glad to hear from any upon this point. The Secretary is Edward R. Stone, M.D., 1539 N. Nineteenth Street, Philadelphia.

—The Paris correspondent of the *Lancet*, Oct. 27, 1888, says that at a recent meeting of the Academy of Sciences, Professor Bouchard communicated, in the name of MM. Charrin and Armand Ruffer, a work on the elimination with the urine of soluble vaccinal substances. The authors show that the soluble substances manufactured by the microbes can traverse the body of the animal and be eliminated with the urine, whilst still preserving their property of conferring immunity. The production of vaccinal matter should be attributed directly to the microbes, and not to the cells of the living organism.

—The latest report of the An Ting Men Missionary Hospital, in Pekin, says the *Ledger*, Nov. 12, 1888, contains some interesting information in regard to certain classes of Chinese patients. Suicides are very common in Pekin, a strong extract of opium being most commonly employed for the purpose, but stabbing with a knife in the abdomen is common. In one case of this kind, which was treated at the hospital, the reason assigned for the act was that the man had applied to a friend for a loan of money and been refused. In order to spite the niggard, he committed suicide, that his spirit might come back and perpetually annoy the latter. Possession by demons or animals is a complaint for which patients constantly demand treatment. The animals in question are most commonly the fox, weasel, hedgehog, snake and rat. Persons possessed of one or other of these are supposed to have extraordinary power in revealing future events, curing diseases, or indicating lucky days and numbers.

HUMOR.

Brown—"You don't look well lately, Robinson." Robinson—"No; I can't sleep at night on account of lung trouble." Brown—"Nonsense; your lungs are all right!" Robinson—"Yes, mine are; the trouble is with the baby's."

Editor—"Uncle Rastus, we want another man at the office to help keep things in shape. Do you think you would like the job?" Uncle Rastus—"I reckon I wud, Mistah Shears; but I dun know. No man kin tell how he wud like editin' till he tries, sah."—*Harper's Bazar.*

Was a Boy Once Himself.—Boy—"Say, Mister, father wants to know what's the cheapest way of gettin' teeth inserted." Village dentist (significantly)—"Well, I reckon the cheapest way that I know is to come and steal my apples when my bull-dog's round."—*Harper's Young People.*

"This is indeed a hand-to-mouth existence," sighed the druggist, as he tore off and licked the postage stamp for a chance customer. "I'm also doing a light business," said the man at the cigar counter; "at least my gas jet seems to be the only thing wanted by half the men who come in."—*Puck.*

In Financial Distress.—Bobby's Uncle James had given him a penny to invest at the candy store, and he darted off filled with glad anticipation. Presently he returned, crying bitterly. "What's the matter, Bobby," inquired his Uncle James, "did you lose your penny?" "N-no, sir," sobbed Bobby, "t-taint lost, it's jest swallered."—*Epoch.*

A Question of Locality.—"This is a very grave case, my man," said a doctor, leaning over a wounded man in a hospital. "Is it really dangerous, doctor?" "Very; you have been injured in the lumbar region." "Now that's just where you're mistaken. I was never in Maine in my life. I got this wound in the Blue Mountain region."—*Harper's Bazar.*

What the Doctor Pronounced It.—"What did the doctor pronounce your ailment?" inquired the wife, with a tremor of anxiety in her tone, as she came into her husband's sick-room. "He pronounced it as if it were spelled bronkeetus," exclaimed the indignant Bostonian, straightening himself up in bed, "and I requested him at once to make out his bill and go."—*Chicago Tribune.*

A Coroner's Verdict.—The following delicious coroner's verdict is in print, apparently a specimen of Baboo English, that is, English as written by a native of India. This was rendered upon an ill-fated Hindoo. "Pandoo died of the tiger eating him; there was no other cause of death. Nothing was left except some fingers, which probably belonged to the right or left hand."—*Boston Med. and Surg. Journal.*

Suspected a Trap.—"Here's an article headed: 'Mavelous Escape of a Distinguished Citizen from a Horrible Death,'" said the dutiful daughter, who was reading the morning paper to her invalid father. "'The friends of Mr. J. Alpheus Bramble were shocked on learning, a few mornings ago, that—'" "Jane," interrupted the irritable parent, "before you read any more of that you will oblige me if you'll look about half way down to the bottom of the article and see whose patent medicine it's advertising."

MARRIAGES.

Theiss—Manton.—On Sept. 25, 1888, by Rev. J. H. Conkle, H. C. Theiss, M.D., to Miss Eva Manton, both of Akron, Summit Co., Ohio.

Mecaskey—Martin.—On Oct. 18th, at Albion, Mich., by the Rev. J. C. Floyd, Dr. J. W. Mecaskey, of Phila., to Mary Katherine, daughter of Dr. R. A. and Mrs. Isabella Martin.

WHOLE No. 1656.] NOVEMBER 24, 1888. [VOL. LIX, No. 21.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

THE DOUBLE ACTION OF MEDICINES AS ILLUSTRATED BY DIGITALIS.

BY BOARDMAN REED, M.D.,
ATLANTIC CITY, N. J.

In the London *Practitioner* for April and May, 1888, there appeared a paper contributed by the writer, entitled "The Primary and Secondary Action of Drugs." It was based upon a somewhat thorough study of the results of experiments on animals by leading German, French, English and American pharmacologists, as well as a considerable clinical experience extending over a period of ten years. In the August number of the *Therapeutic Gazette* of which Professor H. C. Wood is senior Editor, this paper was the subject of a long editorial in which the method and conclusions of the writer were attacked and an attempt made to refute them. The writer replied by contributing to the October number of the same journal an article in which he defended and still further fortified the position assumed. In the same number of the *Gazette* the editors returned to the attack. Thereupon, the following brief rejoinder was submitted. It was declined with the information that the controversy was closed:

In their first criticism of the theory recently defended by me, that most drugs have a double action, the editors of the *Therapeutic Gazette* conceded that "there are certain drugs which in large doses act in a manner apparently antagonistic to the effects of their smaller doses." In the October number of the *Gazette* they go further and admit that "*many* drugs in small doses appear to act in a method antagonistic to that in which they act in large doses." That is getting on.

The elaborate communication contributed by me to the *Therapeutic Gazette* for October, traversed fully the questions between the editors and myself, and though it was sharply criticized in the same number, not one of the points seems to me to have been really answered.

For rejoinder I might well content myself with begging any reader who is interested in the subject and still in doubt about it, to re-read carefully both the criticism and the communication itself.

There is in the criticism, however, a semblance of reply to my argument in so far as concerns digitalis. The editors in their August number had squarely denied that digitalis even in overdoses can paralyze the heart, and with equal positiveness had asserted without qualification or exception, that "the heart is arrested in permanent spasm of its muscle [*i. e.*, in systole] by substances of the digitalis group." In the October number I showed that Nothnagel and Rossbach, two of the most celebrated pharmacologists in Europe, had announced as a result of their minute study of the drug—one of the most elaborate and exhaustive to be met with in medical literature—that large doses of digitalis in the case of mammals *do paralyze the heart*, and that so far from being constantly arrested in systole by overdoses, it comes to a standstill finally, *paralyzed in the opposite condition of diastole.*

Contradiction could not be more positive

and it comes not from me or any obscure person whose laboratory experiments might be questioned, but from authorities of the highest eminence, practical experts in experimentation on animals, and from physiologists thoroughly trained in laboratory work.

It was shown by me, moreover, that Huchard, another eminent transatlantic expert in the same field, had pointed out that it is only in the case of cold-blooded animals, such as frogs, that digitalis arrests the heart in systole, while in warm-blooded animals, including man, it stops it in diastole. Prof. Lauder Brunton, the most eminent pharmacological authority in England, was quoted against the assertion that the heart is uniformly arrested in systole in digitalis poisoning.

Professor Phillips, also of London, and Professors H. C. Wood and Roberts Bartholow of Philadelphia, all noted authors of standard works on Materia Medica, were also quoted to show that digitalis affects various parts of the circulatory apparatus in a two-fold manner. They thus aid in clinching the point that the foxglove is no exception to the rule that the small and large doses of active drugs generally have opposite actions.

The citations from these authorities were clear and emphatic to that extent and quite incapable of being misunderstood by any physician of even average attainments.

How do my critics meet all this array of definite and exact testimony? Their answer may be arranged under three heads:

1. They charge me personally (not Nothnagel, Brunton *et al.*) with not being a trained experimentor on animals, and complain because I did not go into the laboratory and illumine the question by taking the cut-out heart of the frog and administering to it various doses of digitalis. If I had rested the case on experiments of my own, such objections might have had force

2. They try to explain away the statement, cited from Professor Wood's "Therapeutics," to the effect that moderate doses of digitalis cause a strong pulse and high arterial pressure, while poisonous doses cause a weak pulse and "lowered arterial pressure," so as not to admit antagonism between the different ranges of dose. Their explanation, which is in the nature of an hypothesis, is more ingenious than conclusive. I will not stop now to dissect this hypothesis and show, as can be done, that it is not in accord with the views of most other pharmacologists, and that it is quite insufficient to account for all the facts.

They do not have a word to say about the much more pointed testimony to the double action of digitalis cited from Nothnagel and other celebrated authorities.

3. They acknowledge, however, finally, that "digitalis may sometimes arrest the heart in diastole," notwithstanding that in their first criticism they had unqualifiedly declared that it is "arrested in permanent spasm of its muscle"—*i. e.*, in systole. To break the force of this tardy admission, they now claim that this diastolic arrest is not due to paralysis of the heart but to stimulation of the vagus nerve. How then about the still later stage of the poisoning, in which the vagus nerve itself has been shown to be paralyzed?

To clear up this point it is sufficient to refer the reader again to the lucid and comprehensive statement by Nothnagel and Rossbach of the results of large doses of digitalis, cited at length in my previous communication. These authorities show clearly that while vagus stimulation may account, in part at least, for the eccentricities of the pulse in the earlier stages of digitalis poisoning, there results paralysis of the heart muscle itself in the final stages of such poisoning, except in the case of frogs, in which death often occurs in systole before the final paralytic effect of the drug has been attained.

Professor H. C. Wood, the distinguished senior Editor of the *Gazette*, has himself, in his "Therapeutics," furnished several pages of testimony pointing unmistakably to the fact that, while in small doses digitalis is, as he phrases it, "a powerful stimulant to the circulatory system," in very large doses it ultimately leads to heart failure and death. However much one may quibble or split hairs in discussing the supposed action of the drug in detail, the great central fact just stated cannot be gainsaid. Other pharmacologists all corroborate it more or less explicitly, however confused and befogged their testimony may sometimes seem to be by detailed accounts of their demonstrations of the supposed action of the drug on various cardiac structures, including the hypothetical nerves, ganglia, etc., which, following Schmiedeberg, physiologists still assume, though the exact functions of these have not been proved. Indeed, Brunton, the ablest and frankest of all the workers in this field, distinctly says in the last edition of his great work on "Therapeutics"—page 314: "Schmiedeberg's hypothetical schema has

been most useful for several years, but facts which it will not explain are beginning to accumulate, and we must look in another direction for their explanation. The whole question of the action of drugs upon the heart is far from being completely solved."

So much for the evidence from the laboratory concerning digitalis. The experimenters agree that it is highly toxic, easily killing when pushed, and not even Professor Wood will ever succeed in proving that it does so in mammals, at least, by making the heart too strong. Clinical experience is all the other way, and shows emphatically that over-dosing with the drug leads ultimately, and often speedily, to cardiac weakness and death from heart failure. Whether it is only the heart muscle or the hypothetical intra-cardiac ganglia which are paralyzed, is not of vastly great importance, considered from the clinical standpoint.

Right here it is in place to say that it is from the clinical standpoint and for the benefit of clinicians and their patients that I am considering this whole subject. It is only in the hope of advancing in some small degree the transcendantly important art of practical medicine that I have consented to make myself a target for personal attacks by championing a somewhat novel view of drug action, and thus demonstrating that there yet lurks, in some conservative corners of our progressive medical profession, a little of that intolerant spirit which Molière so cleverly satirized by making a candidate for medical honors take an oath never to alter the practice of physic. Yet it has not been intended to say anything not complimentary of the able and earnest men who are engaged in experimenting with drugs upon animals. On the contrary, they are entitled to high praise. Though their results can seldom be received as conclusive till verified at the bedside, very much of their work is distinctly helpful in the direction of advancing therapeutics; and if the theory of the double action were accepted, that large part of the toxicological facts accumulated by them, which, as intimated before, are now comparatively barren and useless to clinicians, could at once be turned to practical account.

The editors of the *Gazette* offer to award me great glory if I will "prove in the laboratory" that digitalis can paralyze heart muscle, and also prove, in the same way, the contrary of various propositions which they lay down. My answer is: 1. That I am not writing up this matter for glory or credit, but for other reasons, as already explained; 2. That other men, who are experts in laboratory work, have demonstrated what is demanded regarding digitalis and have furnished materials, as a result of their experiments, which prove, in my opinion, that all the drugs referred to have double actions.

If the aforesaid editors cannot be convinced by the testimony of eminent authorities in their own special field, they would not believe even one raised from the dead, still less my own testimony, supposing that I could afford to equip a laboratory and find time from a busy practice to make the necessary experiments. If they really doubt that aconitine, veratrine, and viridine have double actions, and will accept as conclusive the experiments of any reputable pharmacologists, I will undertake to furnish the necessary evidence; and in case it should turn out that any of the drugs mentioned has not been sufficiently studied, I will then gladly make additional experiments, either on animals or on men or both, to supply the deficiency. Otherwise it will be quite useless to prolong this controversy. At some future time, however, I may publish numerous reports of clinical cases showing the efficacy of unusually small doses of medicines, administered to antagonize pathological conditions such as could be caused by toxic doses of the same. I hope then to be able to demonstrate at length and with sufficient clearness to convince even the most timid therapeutist that he need not be deterred, by the fear of treading on heretical ground, from curing his patients with the smallest effective doses, whenever these happen to suit best.

Indeed, one of the most satisfactory things about the theory of the double action of medicines is that it affords an all-sufficient scientific basis for maintaining that the small-dose effect, as well as the large-dose effect, is really antagonistic to the disease. It thus quite does away with the necessity for lugging in the irrational dogma of *similia similibus curantur* to account for such cures as those of vomiting by drop-doses of wine of ipecacuanha, or of Fowler's solution, and of diarrhœa by fractional parts of a grain of gray powder, rhubarb, or podophyllin. In short, it affords an intelligible and rational explanation of all curative effects obtained with relatively small doses of tissue-disturbing remedies, whether administered by regular physicians or by homœopaths, when the latter do not administer amounts so infinitesimally small as to be incapable of producing any effects.

STRANGULATED HERNIA; OPERATION AND AUTOPSY.

BY J. M. ANDERS, M.D.,
PHILADELPHIA.

Whilst cases of strangulated hernia are not infrequently met with in practice, strangulation by bands of omentum in unusual situations are not of common occurrence, and are always interesting subjects for study. Without stopping to consider statistics showing the relative frequency of this latter condition—a subject with which the progressive surgeon is already familiar—the following case, which exhibits phases of unusual interest, seems worthy of being recorded.

J. R., 41 years old, by occupation a foreman in a plastering-hair manufactory, had, before his last illness, always enjoyed excellent general health. For several years he had had, however, an inguinal hernia, which occasioned him no trouble, but for which he had worn a suitable truss. On August 18, 1888, he was seized suddenly, while at work, about 9 A. M., with violent, paroxysmal pain, chiefly localized at the intersection of an imaginary line dividing the umbilical and left lumbar regions, with a line connecting the anterior superior spinous processes of the ilia. At first the intervals between the paroxysms of pain were from five to ten minutes, but the pain gradually became more frequent, until it finally was almost continuous. Dr. Strobel was then summoned; he prescribed an opiate and ordered the patient to be taken home. The family physician, to whom I am indebted for the facts in the history of the case up to the time of my own connection with it, was then sent for. During the evening of the same day vomiting set in, and continued at brief intervals. Though the patient's truss had been removed in the morning, the hernia did not appear in the scrotum, and there was at this time neither pain nor tenderness on palpation over the inguinal region.

August 19, 10 A. M. The patient obtained a few hours' sleep during the previous night. The pain at this time was agonizing, the paroxysms occurring in quick succession, while vomiting was also continuous. A hernial protrusion of about the size of a duck's egg (which was about the size of his old hernia) was now found to occupy the upper portion of the scrotum and the inguinal canal; and almost immediately the seat of greatest pain was, as it were, shifted to the same locality. On the evening of the same date, pain continued unabated, and there was stercoraceous vomiting. Efforts at reduction of the hernia were unsuccessful.

August 20, at 6 o'clock A. M., I was requested by the attending physician to see the case with him immediately. The patient was found to be in a state of collapse, vomiting incessantly and suffering greatly from racking pain referred to the protruded mass. The point of greatest tenderness on palpation was at this time about two inches above the inguinal canal, giving rise, when coupled with other symptoms present, to the suspicion that in this vicinity a constriction of the intestine existed. Failing in our efforts to reduce the hernia by taxis, I advised immediate operation. A few hours later, Dr. John B. Deaver performed herniotomy; and upon request, he has kindly furnished a succinct account of the most interesting facts pertaining to the operation, together with the results of the autopsy, which he was permitted to make two days later.

"I saw the case just described with Drs. Anders and Himmelwright, August 20, at 11 A. M. I fully concurred with them as to the propriety of exploring the left inguinal canal, which was the seat of a tumor. The field of the operation, as well as the surrounding parts for some distance, were subjected to the ordinary preparations for a strictly antiseptic operation, and the patient etherized by Dr. Himmelwright. Dr. Anders and my student, Mr. Benjamin Michel, assisting me, I laid open the left inguinal canal and the upper part of the cavity of the left scrotum, by an incision carried over and parallel to the axis of the canal. Both the canal and the upper part of the cavity of the scrotum were found to contain a hernial sac, the contents of which, on opening the sac, proved to be an old omental hernia, there being no gut to be seen or felt. The omentum was slightly adherent to the sac at several points, but was otherwise healthy; this condition of the parts proved that the immediate sufferings of the patient were not due to this mass of great omentum, but, coupled with the symptoms of the case, suggested that the cause of the trouble was higher up. With the approval of Drs. Anders and Himmelwright, I therefore freed the great omentum, gaining access to the abdominal cavity, which was explored with the fingers, but with negative results. The incision was now prolonged upward in the

line of the left linea semilunaris for a distance of one inch, when the abdominal cavity was again explored with the finger, this time detecting an unyielding knuckle of intestine which, to the sense of touch, appeared softer than normal. As this could not be seen, the incision was carried one and one-half inches higher, in the same line as before, when a knuckle of softened and discolored small intestine, constricted by an omental band, was exposed. The constriction was relieved by the knife, so that the small intestine could be moved freely. The diseased portion of the small intestine, as well as the mass of the great omentum which had occupied the hernial sac, was treated with warm towels by Dr. Anders, while I prepared to complete the operation. The color of the intestine having improved slightly under the application of the moist heat, I thought it best to return it, as the patient's condition was now very unfavorable, not permitting me either to resect or to make a temporary artificial anus. The great omentum being apparently healthy, I returned it also. It now remained for me to close the wound, which I did with prepared aseptic silk sutures, carrying them down through the peritoneum, dressing it with wet bichloride gauze, bichloride cotton, and an aseptic bandage. During the operation, bichloride solution of the strength of 1 to 3,000 was used for the sponges and for irrigation, till the abdominal cavity was opened, when it was substituted by hot water. I saw the patient at 11 P. M., the same day, and found him comfortable; he had not had a return of the agonizing pain of which he complained before the administration of the anæsthetic. His general condition was anything but favorable; he was profoundly shocked, and did not show any tendency toward reaction, notwithstanding the use, both internally and externally, of the remedies proper in these cases. I saw him again on the morning of the following day, when it was only a question of his living a few hours. He died at 2.30 P. M., August 22. In the presence of Drs. Anders and Himmelwright and Mr. Michel, I made the autopsy. The body was that of a well-preserved man. I opened the abdomen through the linea alba; all its contents were found normal except the portion of the great omentum that had occupied the site of the left inguinal canal and the upper part of the cavity of the left scrotum, and the knuckle of the small intestine, which had been the seat of constriction; both these structures were gangrenous."

After the operation Dr. Deaver expressed the opinion that the patient could have been relieved, and with greater dispatch, by an abdominal section through the median line. He thought, however, that there were probably few experienced surgeons in such a case who would not have first explored the inguinal canal, which was the seat of the tumor, and subsequently have extended the incision sufficiently to examine thoroughly the contents of the abdomen. Had this patient not exhibited a protrusion from one of the hernial orifices, and yet displayed the same symptoms, he would have advised an abdominal section.

Obviously, in the light of the developments of the post-mortem inspection, the mass of great omentum separated from the hernial sac should have been tied off and not returned to the abdominal cavity.

THE PREVENTION OF CONCEPTION.

BY ERNEST C. HELM, M.D.,
BELOIT, WIS.

I have been greatly interested in the discussion of this subject, and of "The Conjugal Question," as the various articles and Editorials on them have from time to time appeared in the columns of the MEDICAL AND SURGICAL REPORTER. These questions are so difficult to handle, that they are greatly neglected; yet a calm, clear, clean treatment of them is of the utmost importance. These matters should be thoroughly understood by the physician; and I think, in certain selected cases, his duty to his patients and to humanity should compel him to explain them freely and fairly. Upon a careful consideration of them depends, in large measure, the welfare of the community, and it is with extreme diffidence that I approach the subject.

Such various views are held, not only among the laity, but also in our profession, that the broadest charity should be used in judging one who has the temerity to differ at all from the accepted opinion of ages. In a former number of the REPORTER, one physician thought it an insult to the young wives of this country to suppose that they would ask what the consequences of sexual intercourse are. I can, however, see no insult to them in such a supposition; for they *do* ask the question. Not all, perhaps, but it is no tribute to their intelligence, if they blindly accept intercourse for the pleasure it gives them or their husbands,

without thinking or asking what the consequences will be. They ought to know; it is their duty to know; and they should conceive and bear children, not unwillingly or unknowingly, but in the full knowledge of what they are doing.

Many girls marry at fifteen or sixteen years of age, and, if strong and well developed, it may be that physically they can endure frequent pregnancies without injury to themselves or their offspring. In such cases it may be that the physician would not be justified (if asked) in offering suggestions regarding the prevention of conception; and if, simply for social reasons or to escape the pangs of child-birth and the trouble and expense of rearing children, the mother should visit the abortionist, then the sin would be upon her own head.

But even in such a case is it wise for this young girl "in her teens," and scarcely out of short dresses, not only to assume the new and strange duties of housekeeper, home-maker and wife, but at the same time that most sacred of relationships—mother? We find her married, and cannot change that; so it will do no good to try to escape the dilemma by saying that she should not have married. She *is* married; now shall she become a mother at once? Common sense would suggest that, now that she is married, sexual intercourse should be at rare intervals, and it would be better for her if she should not become pregnant for a few years. She will then have become more mature, and can better b ar and rear children. Child-mothers do not make the best mothers, and child-bearing often wrecks their physical systems. Young husbands and wives are themselves developing, and are just beginning to enjoy life Would not the first few years of their married life be far happier if they could devote it to understanding each other, and securing and making a real home, so that when babies should come they could the better be cared for?

Even granting that the physician should say nothing here, it is different in the case of the young, sickly, immature girl, who has been so injudicious as to marry, though utterly unfit for it. Now if she soon conceives, and pregnancy, instead of restoring her to health, as it may do, carries her to the verge of consumption or the grave, and the child is feeble and puny, has the trusted family physician no duty to perform toward this poor girl? Her happiness, her life even, are in his hands. Must he be content with chiding her for her early marriage, and telling her that she must bear the consequences? He may feel sure that another pregnancy may be fatal to her, and probably will be: would it not be proper then, quietly yet earnestly, to talk with the young husband and wife—mere children as they are—about avoiding frequent intercourse?

But if he stops here, is his duty fully done? I once heard a famous professor, in a case in which the young mother, scarce twenty-two years old and very slight and feeble, gave the history of three child-births and thirteen miscarriages in seven years, say, with a shrug of his shoulders: "The only thing to do with this case is to chain up the husband." The woman's health was of course greatly undermined, and the youngest child, sandwiched in between the miscarriages and reared by this unfortunate mother, was in a very precarious condition. Now should this physician have been content with giving advice which he knew must be disregarded, or at least would be?

Very young wives. no matter how good their health, are apt to break down under the strain of frequent child-bearing. To whom can they come for relief if not to the family physician? If he will not give them some simple method of preventing conception, they may when pregnant seek the services of the professional abortionist. Would not these vampires cease to exist if the family physician did his full duty by his patients?

Foreigners call abortion the "American crime"—but it is a misnomer. Abortion is frequent among American women because they are not as robust as certain other classes. but the abortions are not generally brought on by themselves or their physicians. They are intelligent, and may take measures to prevent conception rather than run the risk of accidental abortion, which would be so apt to follow conception if they are in feeble health.

When I hear men gravely denouncing the prevention of conception as a crime, I only wish that they could bear and rear one child. Women, as the weaker and finer creatures, suffer more than we would. Let us put ourselves as far as possible in their places, and scan the subject from their standpoint. What are their wishes in the matter? If they have decided preferences, they should be consulted; for they are equal partners in the marriage relation. Their wishes and interests are too often ignored, either from selfish or puritanical motives or from sheer carelessness on our part.

It seems to me that physicians shrink unduly from this question, lest their opin-

ions should become public property, and removal of the ever-present fear of conception should open the flood-gates of immorality and indiscriminate and illegitimate intercourse. These fears, I think, are groundless, for I do not for an instant believe that the reason our girls are pure and chaste is because they dare not be otherwise lest they become mothers. If anyone has such an opinion of American girls and women, then his acquaintance with them must be very limited. Purer girls and truer and more devoted wives do not exist than come from the ranks of our countrywomen.

Physicians know as well as it can be known that motherhood is a noble mission, perhaps the noblest open to woman; but to spend life from eighteen to forty-five bearing and rearing children is not unlikely to sap the vitality of any woman, and prevent that development of mind and body, that improvement of children and of the home-life which should be the aim of every true wife and mother. Furthermore, too frequent conceptions and pregnancies are not good for the mental and physical well-being of the children. This mother with too many children has not time to devote to their rearing and culture, but her entire time is occupied with the baby just born, or about to be born. She is shut out, to a great degree, from the social intercourse which is so dear to woman; all her chances for mental improvement are cut off; the cares and worries of her condition make her irritable and petulant, and the real pleasure she takes in the society of her husband, and in the neatness and home-like atmosphere of their home is greatly lessened.

True home-life depends on the wife and mother more than on anyone else. She must make home the brightest spot on earth to her husband and children; and if she fails in this, their future prospects are not very bright. Common justice demands that she be given time to think and plan for the peace, happiness, and purity of her home. There is something sacred and holy in the married state, where two young people start out to make a new home, a place of refuge, where care and worry shall be banished as far as possible. and where these two shall truly be one. The sacred mystery of pregnancy and motherhood draws husband and wife closer together, and in their love for and interest in the life and welfare of the babe God has entrusted to their care, they draw nearer each other, and their home-life becomes brighter and purer. Their love and ambition centre around their offspring, and they are better citizens for this new responsibility. If several more are added to the number they are to rear, still they may be glad and willingly undertake their care and education.

But let us go on with our picture. Children come thick and fast, the poor mother has not one child provided for before she must prepare for another, or for twins perhaps. There is a constant succession of children, and this woman—the wife, the mother—becomes in reality a mere child-bearing machine. The home-life is devoted to caring for the babies, and the lives of the little ones are spent in tending the smaller ones. These constant burdens tell on the mother in many ways, and the father is unable to meet the expenses of such a large, ever-increasing family; so he either must live in an humbler way, or he may get more and more in debt, or in desperation, the abortionist may be called in to keep peace in the family, and the wolf from the door. Then at last the poor woman may find respite, but at what a fearful cost! with moral sense blunted, and perhaps her physical health impaired or ruined. Many otherwise happy homes are wrecked on account of too frequent maternities, and the lives of fathers and mothers rendered a burden. It is true that large families are often very happy ones; but times are changing: competition is daily growing more fierce, while expenses are piling up, and women are more sedentary and less robust than formerly, and fathers are not as capable of supporting large families, or mothers of rearing them, as in the "good old times."

My invariable practice when approached by a husband or wife in regard to the means of preventing conception has been to say: "There is a sure way: do not marry; but if you are married, sleep apart and never have sexual intercourse." I fear, however, that this chaste advice has never been followed; and as long as human nature remains unchanged, I do not think it is likely to be. Until a very recent period, I thought that a physician was not justified in giving any other advice; but now I am looking for more light on the subject. It seems to me that, even if they were instructed in regard to the methods of preventing conception with which physicians are familiar, self-respecting women would become pregnant fully as often as the welfare of themselves or their children would permit.

The Medical and Surgical Reporter for November 3 describes several methods

which are comparatively *simple and harmless*. The question as to their harmlessness is discussed there; but even if they are not perfectly harmless, I think the reader will agree with me they are far less likely to be harmful than too frequent pregnancies.

The advice of the physician on this important subject should not be indiscriminate; but in selected cases, is it not his duty to tell his patients some simple means of avoiding too frequent conception? Would not such advice conduce to the welfare and morality of those entrusted to his care? The vicious and immoral do not ask for or need this advice, for they have plenty of devices of their own; but as physicians, as humanitarians, should we withhold it from those who seem to need it very much, and denounce the prevention of conception as a crime second only to criminal abortion?

This question is daily becoming of greater importance. How shall we meet it?

Society Reports.

AMERICAN ACADEMY OF MEDICINE.

12th Annual Meeting, at New York, Tuesday, Nov. 13, 1888.

FIRST DAY, MORNING SESSION.

The President, Dr. Frederick Henry Gerrish, A.M., M.D., of Portland, Maine, in the chair.

Dr. Leartus Connor, of Detroit, Mich., read the Report of the Committee on the Requirements for Preliminary Education in Medical Colleges in the United States and Canada, and referred to the methods of determining whether or not the colleges fulfilled the statements made in their announcements. One of these was by means of decoy-letters This plan last year indicated that the majority of the colleges fulfilled their statements. Another method of judging is by a disinterested examination of the graduates, such as the examination for the army or navy. Positive data are not at present available; but in regard to these examinations the principal deficiency seems to be in the preliminary education. The general verdict of editors is that the average doctor is lamentably deficient even in what is known as common school education.

There are in the United States, 116 medical schools. According to their announcements, 89 exact certain educational requirements; but 19 of these require no more than they can help. It is futile to endeavor directly to influence medical colleges to make these requirements. They can be obtained only by awakening in the mind of the profession and people a sentiment that a definite preliminary education is necessary to the medical student.

Dr. A. L. Gihon, U. S. N., offered the following resolution, which was adopted: *Resolved:* That the American Academy of Medicine expresses its approval of the aid afforded the cause of higher medical education by the College of Physicians and Surgeons of New York, in its recent requirements for matriculation, which the Academy commends to the profession as worthy of adoption.

Dr. J. C. Wilson, of Philadelphia, read a paper on

The Causes and Prevention of the Opium Habit and Kindred Affections.

These affections are prevalent, but we possess no reliable statistics concerning their frequency. The causes may be grouped under three heads: First, Example, as shown in the case of those who become opium eaters through the example of friends. Second, Suggestion, as shown in those who fall into these habits through the reading of literature concerning it, or from familiarity with the drugs, as in the case of doctors, druggists, nurses and students of medicine. Large numbers contract the opium habit from these causes in the absence of sickness and physical pain. Third, Medical Prescriptions. It is an unfortunate fact that most of the victims of habitual vicious narcotism become so through the prolonged abuse of narcotics originally prescribed by a physician for the relief of pain.

Among the measures for the prevention of such habits, are:—First, the dissemination of a wholesome knowledge of the methods by which the opium habit and kindred affections are induced; of the serious character of these affections, and of the dangers attendant upon an ignorant and careless employment of narcotics. Second, a reasonable and temperate presentation of the facts in the popular works upon hygiene. Third, the exercise of every possible precaution on the part of physicians in prescribing narcotics. It is good practice to keep the patient in ignorance of the character of the anodyne used, and of the dose; physicians should personally control, as far as possible, the use of such drugs, and see that they are taken infrequently and in the

minimum amounts capable of producing the desired effect. The occasional alternation of anodyne medicaments is desirable. Prescriptions for drugs of this kind should not be renewed by druggists without the written order of the physician. Finally, a merely palliative treatment should not be allowed to assume too great importance in the management of curable painful affections. Under no circumstance except in the final stages of hopelessly incurable painful affections, should the hypodermic syringe be placed in the hands of the patient Uniform and efficient laws to regulate the sale of narcotic drugs are desirable Existing laws relating to this subject are a dead letter; they are neither adequate to control the evil nor is their enforcement practicable.

Dr. R. L. Sibbet, of Carlisle, Pa., thought that the physician should not tell what he is giving when he prescribes opium. He also thought that we should never write a prescription in which the word opium appears.

Dr. Leartus Connor, of Detroit, considered it unsafe for the physician to administer a narcotic in his own family He could give a large number of instances in which wives and other members of physicians' families had become addicted to the use of opium in this way. It is unsafe for the physician to administer opium to himself.

Dr. Theophilus Parvin, of Philadelphia, read a paper on the

Importance of Practical Obstetrics

in the course of instruction given by medical schools. A recent visit to Munich, where he spent some time observing the method of teaching obstetrics in the University of Bavaria, pursued by Professor Winckel, made him conscious of the great deficiencies of the American plan of obstetric instruction. The science of obstetrics is admirably taught in our medical schools, by pictures, models, illustrations of various sorts, with preparations of pelves, etc., but the vast majority of American medical students graduate without having witnessed a case of labor. In many medical schools, the diagnosis of pregnancy by auscultation and by palpation is not taught so that the graduate sees with his own eyes and feels with his own hands. There is also reason to believe that the mortality of private practice is greater than that of hospital practice. Then, too, the unqualified obstetrician contributes largely to the work of the gynecologist. Whilst attendance on poor women at their homes is better than no practice at all, yet the student will derive more benefit from the study of cases collected in a maternity hospital, where many cases can be studied under the instruction of a competent teacher. The practical teaching of obstetrics is to be directly associated with its scientific instruction. There should therefore be a maternity belonging to every medical school in which obstetrics is taught. In large cities there would be no trouble in obtaining sufficient material for this method of teaching. Through the efforts of the author, the trustees of the Jefferson Medical College authorized the establishment of a maternity department in connection with the hospital. Thirty-four women have been confined without a death. The room being insufficient, an out-door department has been established. Here there have been 151 applicants, of which number 106 have been confined, with but one death, which occurred two weeks after labor. The cause of death was not positively ascertained.

The author then described the methods employed at the Bavarian University, basing his remarks on a report furnished by Dr. J. Clifton Edgar Obstetrics is there taught by (1) didactic lectures; (2) obstetric clinics; (3) touch courses; (4) operation courses on the phantom; (5) management of labor cases; (6) bedside instruction in the puerperal wards. The student is required to attend obstetrical clinics for nine months. In this time he would, at a low average, thoroughly examine eighteen gravid or parturient women, and deliver four women.

In concluding, Dr. Parvin said: "Why would it not be wise for this Academy, which should be a light and a guide to the American profession, leading it to higher and giving it larger views on its duties and responsibilities, declare, with hearty unanimity, that practical obstetrics should be made a part of the regular course in every medical college? With the seal of your approval, those who are laboring to this end will be given strength and hope.

"May the time soon come when every medical school upon the continent, which does not take steps to make this necessary reform, shall perish under the common and condign popular and professional damnation!"

AFTERNOON SESSION.

Dr. F. H. Gerrish, of Portland, Me., delivered the

President's Address.

Reference was first made to the necessity for something more than a mere grammar-

school education as a preparation for the study of medicine. The course of a medical student without proper preliminary education was traced. Until recently any male of the human species, who could pay the necessary fees, found no difficulty in entering a medical college. A few years ago several medical schools established a preliminary examination. This was attributed by the speaker largely to the action of the Illinois State Board of Health, to the effect that if the schools wished their diplomas to be recognized in that State, they must have a preliminary examination. He thought that the labors of the Academy should be directed to the elevation of the standard of medical education, rather than to the investigation of scientific problems.

The next portion of the paper was devoted to a consideration of the methods by which the membership of the Academy could be increased.

The President then referred to certain amendments which had been proposed at previous meetings. One of the amendments considered related to Art. VIII, Sec 1, which now reads: "The Fellows of the Academy in their relations with each other and with their fellow-men, agree to be governed by the principles embodied in the present Code of Ethics of the American Medical Association, and by the Constitution and By-Laws of the Academy." The amendment suggested is: "The Fellows of the Academy will be governed by those principles which actuate educated, cultured and honorable men in every profession, and by the Constitution and By-Laws of the Academy." The speaker favored the adoption of the amendment.

Never before, he said, has it been appropriate to address the Academy as "Ladies and Gentlemen," but to-day it is my privilege to make this significant expression. It is neither creditable to our country nor in keeping with the liberality which theoretically characterizes our institutions, that a discrimination should so long have been made against women in scientific associations. It is noteworthy that some of the stanchest upholders of a strict preliminary examination, as ascertained by the detective work of our committee on the subject last year, were the schools managed by women.

Since the last meeting, several members of the Academy have died, and Dr. Gerrish spoke briefly of each deceased member.

In order to facilitate the procuring of essays for the annual meetings, it was suggested that a special committee charged with this work be appointed. In reference to the Congress of American Physicians and Surgeons, he thought it advisable for the Academy to consider the expediency of associating itself with the other societies composing the Congress, thus bringing the Academy into more prominent notice than it has hitherto enjoyed.

Dr. R Lowry Sibbet, of Carlisle, Pa., read a paper entitled:

A Few Words Concerning our Academy.

The Academy was organized in 1876, at a time when the standard of medical education was at its lowest point. Medical institutions were numerous, and their doors were thrown open to all, irrespective of qualifications. At this time there were also at least a dozen of so-called "diploma-mills." It was at this period that the Academy began to explore these novel methods of manufacturing medical practitioners. The addresses by the President and the papers by the Fellows have generally been on some semi-medical subject, and have been widely distributed among professional and educated classes. These addresses have also pointed out the true and only method by which men may become safe and honorable practitioners. The Academy has strongly insisted upon the necessity of preliminary education. At the time of the organization of the Academy, in no State were there laws relating to the practice of medicine that could be enforced. Most of the States now have laws which can be carried out, and many have State Boards of Examiners Graded courses have been adopted in the best medical schools, with preliminary examination and frequent written examinations. The "diploma-mills" no longer exist. This is the only association in which the addresses referred to could have been made, because the sentiments expressed in them were too much at variance with the sentiments of the majority of the profession.

The Academy is the only society in which an Academic qualification is required. There are three departments of activity indicated in the organic law of the Academy: 1, the reading of papers on what may be called the higher science of medicine; 2, the exposure of imperfect methods of medical education; and 3, the bringing into the Academy of eligible members of the profession. The Academy had set a high standard for admission, but he believed that the doors should not be closed against those eminent practitioners who, although they did not possess

the degree of A.B., had pursued protracted courses of preliminary study in literary schools.

Dr. George Jackson Fisher, of Sing Sing, N. Y., read a paper entitled:

The Famous Historic Masters of the Healing Art were Men of Classical Education;

in which he gave, at some length, an instructive review of the history of medicine. He then referred to the extent of medical literature, and to the necessity of being trained to study and research as a preliminary to entrance into the sacred temple of Æsculapius. He emphasized the fact that all the enduring literature of medicine, and all the substantial improvements, discoveries and progress through all time have emanated from learned and talented men; that scarcely anything is owed to the illiterate of our profession The paper concluded by urging the necessity of keeping a vigilant guard at the doors of medicine, and if possible of preventing any from entering who are not "duly and truly prepared"—any who are not possessed of kindness of heart, of good common sense, of fair ambition, and of sobriety, honesty and industry.

Dr. L. Duncan Bulkley, of New York, read the final paper, on the

Relations Between the General Practitioner and the Consultant or Specialist.

In a previous paper the author had shown that specialism is a necessary and healthy outgrowth of general medicine. The object of the present communication was to point out the reciprocal relations which should exist between the general practitioner and the consultant or specialist.

The annual banquet was held Tuesday evening.

Wednesday—Second Day.

MORNING SESSION.

Dr. Charles Carroll Lee, of New York, read a paper on

The Necessity for Post-Graduation Instruction

in the present state of American medical education.

The first Post-Graduate Medical School was opened in New York in 1882. There are now six in operation in different medical centres. These courses are attended by practitioners anxious to brush up on certain subjects. Some of the colleges strive to provide clinical instruction for medical men, but the means at their disposal are not sufficient to provide the instruction required by practitioners. The post-graduate schools are continually increasing in popularity. Here the student in any special branch is able to devote his entire time to that subject. He is also able to follow the practice of a number of experts, instead of being bound down to the methods of a single medical man. For one mature enough to observe and judge for himself, the benefit of this is obvious. It is difficult to conceive how London, Berlin or Vienna can offer greater facilities for clinical teaching than are to-day available in this city. To the medical teacher, a frequent European visit is desirable, not only to perfect his methods of instruction, but to broaden his mind; but the time has arrived when, if the American teacher of medicine does his whole duty, the American student should lack no practical knowledge of his profession.

Dr. Henry I. Bowditch, of Boston, presented a paper entitled:

Tolerance and Intolerance in Medicine; Codes of Ethics.

What code of ethics should the Academy adopt? The author took the ground that tolerance and intolerance are two great moral forces in the world at large, and that in the line of resultant of these two powers, the world has been and will be forever carried forward. History shows how these forces at times have actually changed places, and made vice appear to be virtue. Hence they must be used cautiously and understandingly. Turning to medicine, he found that intolerance had almost invariably been ready to oppose any new idea. Ambroise Paré, Jenner, etherization and Morton, thoracentesis by Wyman's method, were brought forward as examples of the truth of the above statement. Tolerance has, however, always come to the rescue.

The author next referred to the American Medical Association and to his great interest in it in its early days, and spoke of the gradually developing tyranny of its "Code." He called attention to the action of the American Medical Association last year, preparatory to voting that no signature to codes should be required hereafter. The expulsion of the New York State Society was spoken of. In this connection he referred to Homœopathy and Eclecticism, and expressed freely his disgust at the tyranny exhibited at the time of the expulsion of the Homœopathists from the Massa-

chusetts Medical Society. He gave his testimony, from personal knowledge of some members of these two sects, as to the integrity and intelligence of some homœopathists. He advanced the opinion that the Academy will not recover its just position until it rescinds the vote adopting the Code of Ethics. He asserted that the only true code, viz.: "that of the gentleman," is the Golden Rule of "doing unto others as you would have them do to you."

He concluded with the following words: "Gentlemen of the Academy! if all of us would make that divine rule the guide of our professional relations, tolerance and intolerance would join hands in peace; and this Academy, if it could induce all physicians to act upon it, would have accomplished one of its highest missions. God grant that this body may, with each year of its growth, by the work of its individual members and by its own joint labors, tend to bring the whole profession of America up to higher grades of thought, of sentiment and of action, so that we may at length really become what we have hitherto but with unconscious falsehood claimed to be, a truly liberal profession."

Dr. Charles McIntire, of Easton, Pa., read a paper entitled:

Which is the Liberal School?

The author had been led to write the paper by a letter received from a homœopathist, who was in other respects qualified for admission to the membership of the Academy. The question was: Does that branch of legally qualified practitioners of medicine, self-called regulars, show illiberality in its professed rule of non-intercourse with any branch that professes to hold any exclusive dogma? Or is the illiberality shown by those who profess to believe in an exclusive dogma, while they have given up its practice? The author concluded that the illiberality is shown by the latter class.

The consideration of the following amendment to the Constitution was taken up: "The Fellows of the Academy will be governed by those principles which actuate educated and honorable men in every profession, and by the Constitution and By-Laws of the Academy."

After a prolonged discussion, the amendment was laid on the table for one year.

The following resolution was presented by the Council and adopted: "That the Academy heartily endorses the suggestion of Dr. Parvin, that practical obstetrics should be made a part of the regular course in every medical college."

Dr. Charles C. Bombaugh, of Baltimore, read a paper on the

Multiplication of Useless Drugs.

The old polypharmacy was first contrasted with the greater simplicity in framing prescriptions which prevails in our day. In the earlier days there was a sublime disregard of compatibility. What made the farrago worse, were the crude and often repulsive forms in which ingredients were presented, so different from the active principles and elegant preparations to which we are accustomed. He then referred to a variety of interesting considerations connecting past experience with present progress.

In dealing with his subject, the author referred to the continually increasing unwieldiness of the U. S. Dispensatory. The index of the fifteenth edition extends through 76 three-columned pages embracing about seventeen thousand names of medicinal substances. Deducting one-third—a liberal allowance—for repetitions, there are, in round numbers, eleven thousand. Of this number, he thought that ten thousand could be transferred to the *Index Expurgatorius*, without being seriously missed. Of the 324 constituting the primary list, it has been shown that 108 (one-third) are very active; 100 frequently do their work; and 116 are untrustworthy. In this connection, reference was made to the very limited number of remedies deemed worthy of classification in Dr. Wood's Therapeutics. In the sixteenth edition of the Dispensatory, there is an addition of fifteen pages to the index—a total of ninety-one pages. The editors intimate that they have discarded some of the material they considered "effete," so that, although they added 600 pages, the net increase was only 167 pages. As it is time to commence the discarding process and throw overboard the rubbish, this preliminary rejection is most welcome. There is an irruption of newly discovered medicines and newly devised combinations, which demands arrest. The only ground for tolerance is that now and then one comes to stay with the stamp of authoritative approval.

Dr. Bombaugh spoke of the declining sovereignty of empirical conclusions and the coming reign of pharmacology, which is concerned with the action of drugs on the healthy body. The time has come for dependence upon experiments with medicinal agents upon animals. Among the reasons

for hastening the coming revolution is increasing recourse to remedial measures other than the administration of drugs. More and more reliance is placed by the practitioner upon such agencies as the electric current, massage, dietetics, treatment of systemic conditions or diatheses, germicides, antiseptics, disinfectants, sanitation or State medicine, prophylaxis or preventive medicine; but while we are grateful for these acquisitions, and while we welcome additional contributions to a list of positive medicines which is conspicuous for insufficiency, let that gratitude and that welcome be a standing protest against mere numerical preponderance.

Dr. H. A. Johnson, of Chicago, read a paper on the

Influence Upon Medical Education of the Illinois Medical Practice Act.

The Illinois State Board of Health was created in 1877. One of the first acts was the passage of a resolution that the diploma of a college graduating two classes in one year would not be considered in good standing after July 1, 1878. This compelled some of the prolific schools to adopt a single graduating term. In 1880 the Board made a comprehensive study of requirements of medical schools. In 1884 the Board adopted a schedule of the minimum requirements for graduation in the State of Illinois. This has led to an increase in qualifications required by many of the schools. There are now 114 colleges which require evidence of preliminary study as a condition of admission. In 1883 there were only 43. Forty-three colleges now exact a three-year course, as compared with 22 in 1883. The Board has now adopted the following resolution defining the phrase "Medical Colleges in good standing" to mean "only those colleges which shall, after the sessions of 1890–91, require four years of professional study, including any time spent with a preceptor, and three regular courses of lectures, as conditions of graduation; and shall otherwise conform to the schedule of Minimum Requirements heretofore adopted by the Board."

One of the principal causes of efficiency of the Illinois Board is the fact that it is a "mixed" board. At this time the numbers who gain access to our ranks are not so numerous, but they are better qualified; and there are, therefore, not so many inferior men to struggle for existence. The percentage of graduates to students is lower, which means a higher standard of attainments.

The following papers were read by title: The Treatment of Uterine Disease by other than Surgical Means, by Dr. W. F. Waugh, of Philadelphia; The Evils of a Medical Dialect separated Widely from Classical English, by Dr. Edmund Andrews, of Chicago, Illinois.

Ninety-eight new members were then elected.

The following Honorary Members were elected: Dr. J. H. Rauch, Springfield, Ill.; Sir Joseph Lister, London; Sir Spencer Wells, London; J. Lucas Championnière, Paris; Dr. H. P. Didama, Syracuse, N. Y.

Officers for ensuing year: *President*, Dr. Leartus Connor, Detroit; *Vice-Presidents*, Drs. Peter D. Keyser, Philadelphia; L. Duncan Bulkley, New York; Theophilus Parvin, Philadelphia; George J. Fisher, Sing Sing, N. Y.; *Secretary and Treasurer*, Dr. Richard J. Dunglison, Philadelphia; *Assistant Secretary*, Dr. Charles McIntire, Jr., Easton, Pa.

Place of next meeting, Chicago, Illinois.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, November 1, 1888.

Dr. T. M. Drysdale in the chair.

Dr. L. J. Hammond reported a case of

Pyosalpinx.

N. J., 22 years old, had one child three years ago. Since that time she has not felt well, has had frequent attacks of pain in the pelvic region, confining her to bed for weeks at a time. About nine months ago she had a hemorrhage from the uterus lasting three weeks, and followed by a purulent discharge, accompanied with severe pain and great tenderness of the abdomen, especially low down, obliging her to remain in bed two weeks. After this time she resumed her occupation, that of a laundress, until four weeks ago, when the pain became so intense that she was again obliged to go to bed, where she remained one week without medical attendance. At this time I found her with a temperature of 100°, pulse of 120, abdomen tympanitic and so very tender that she could not bear the weight of my hand upon it; she also had menorrhagia. Digital examination was deferred until the next day, owing to the great distention of the bowel with feces, which naturally increased the pain. Upon examination per vaginam, I found a uterus very much enlarged and bound down firmly posteriorly,

together with a large boggy mass on the right side, which was very sensitive to touch. An immediate operation was advised, but was delayed, owing to the absence of relatives, until Oct. 18, when, with the assistance of Dr. J. M. Baldy, the abdominal cavity was opened and a large abscess, with pyosalpinx, was removed from the right side. Great difficulty was experienced owing to extensive adhesions. Several small pus-pockets were ruptured during the removal, and about an ounce of pus was discharged. The left ovary was not removed, it being apparently healthy. After thorough irrigation a glass drainage-tube was inserted, and was replaced on the fourth day by a rubber one, which was removed in 26 hours. It is to-day just two weeks since the operation and the patient is well. At no time did the temperature rise above 99°½.

Dr. J. M. Baldy said that it had been stated in the Society by a member that he had never seen pus in a tube primarily. The specimen presented was interesting in that connection, as there had been pus in the tube as a primary condition. There was not pus present then, as the specimen had been cut open and had been for a long time in alcohol. There were two sacs in the ovary; one contained pus, and the other a blood clot as large as a walnut.

Dr. M. Price, in answer to a question whether the matter contained in these abscesses was really pus or not, said there could be no question but that it was pus. He was quite sure that it had been examined under the microscope.

Dr. B. F. Baer thought that he was the culprit referred to by Dr. Baldy. In the discussion of this subject before the Society, last winter, he was reported as having made the above statement; but he had been misunderstood. What he really did say was that, in his experience, primary pyosalpinx was a rare disease; that in the uterine appendages which he had removed, the condition was an inflammatory one, involving the tubes, ovaries and pelvic peritoneum, which had resulted in gluing or matting together the organs; but that he had failed to find pus contained in the tubes and nowhere else; that in the pus cases with which he had met, there was a condition of abscess in which it was difficult to tell whether the disease had originated in the tube, in the peritoneum, or in the cellular tissue, so extensive was the destruction of the tissues and organs in these cases. It would be a very sweeping statement to say that primary pyosalpinx never occurred, and he did not wish to be misunderstood as making it. His experience during the past year confirms the views which he then expressed.

Dr. Hammond said there was no question about there being pus in this tube. The tube was larger than his thumb and thoroughly distended with pus.

Dr. George Boyd exhibited a

Multilocular Ovarian Cyst.

The ovarian cyst which I have to show in connection with the short history of its growth, I think is of some interest.

Mrs. D., 27 years old, primipara. I was called to see her early last July. I found her advanced in pregnancy. She seemed well, with the exception of the fact that both legs were œdematous. This had caused her some alarm. The urine, on analysis, being excluded as a cause of this swelling, it was attributed to venous obstruction by pressure. She fell in labor Aug. 7, and, with an easy delivery, gave birth to a female infant weighing 8 pounds. I applied the binder, as is always my custom. The uterus was well contracted and its outline regular. There was no evidence of any tumor. On the eleventh day, she was out of bed and about, doing her household duties, feeling well, although the lochia was greater than it should have been. At the expiration of two weeks I left her doing nicely. Sept. 19, about three weeks after my last visit, I was called again to see her. She stated that she was losing blood and also that the stomach was swollen. She complained of pain in the left ovarian region. An examination showed a tumor the size of the uterus at the third month of gestation. It occupied nearly a central position, more to the right of the median line, on the opposite side from where she complained of pain. In three weeks more it had attained twice the size and showed marked fluctuation. Dr. Noble saw the case with me, and together, after a careful examination, we diagnosticated a thin-walled cyst (ovarian or ligamentary). It continued to increase in size very rapidly, and now was above the umbilicus. The pain she complained of was growing more severe, and she was losing flesh. Oct. 18, a little more than two months from her lying-in, with the assistance of Drs. Kelly and Robb, I removed the growth. The operation was of no unusual interest. The cyst was tapped and delivered; there being no adhesions and the tumor having a good pedicle, it was easily removed. It sprang from the right ovary. The patient has made a good recovery. Her temperature

was at no time higher than 99° Fahr. So little was the shock that at the end of the first week, the baby, which had been nursing, was returned to the breast. The points of interest in the case are these: first, an ovarian tumor, not complicating labor; second, the operation performed during lactation; third, an ovarian cyst containing nearly a gallon of fluid, still remaining unilocular.

Dr. William Goodell gave the history of a case of

Double Intra-ligamentary Cysts.

The woman, 30 years old, had been infected with syphilis, from which she had suffered with constitutional symptoms. Two tumors had been discovered a year ago. Her health had failed rapidly, and œdema of the upper and lower extremities was present. The womb was so closely adherent to the tumors, and they were so immovable, that a diagnosis of one multilocular intra-ligamentary cyst was made. At the operation, performed at his private infirmary, Oct. 15, an intra ligamentary cyst of each ovary was discovered, which demanded long and difficult enucleation. They were both extirpated without leaving a pedicle behind. The broad-ligament capsules being thin, were torn in shreds. These were trimmed and tied, and many bleeding vessels were secured. Deeply seated oozing, from vessels which could not be reached, was thought to have been controlled by Monsel's Solution. Two other small cysts were now discovered, apparently wholly independent of the ovarian cysts. As they were too deeply seated and too adherent to the rectum on one side and the cæcum on the other, they were not removed, but were freely incised and cleansed. Many intestinal adhesions had also to be severed in the removal of the larger cysts, which weighed, approximately, ten pounds on the left side and five on the right side. After careful and repeated flushings of the abdominal cavity, a large drainage-tube was put in. Within two hours, serious hemorrhage took place and much blood escaped from one of the tubes; but as it gradually grew less the wound was not reopened, and in twelve hours it ceased. Five days after the operation, when Dr. Goodell was about to take out the tube, high fever set in, preceded by chills, and the tube was therefore not removed. On the next day, a deep-seated abscess burst and its fetid contents escaped through the tube, poisoning the air of a large room for several days. Later a rubber drainage-tube was inserted. Two weeks and a half have now elapsed since the operation, and the woman is doing well; that is to say, her temperature and pulse are natural, and the abscess has nearly healed up; but her convalescence is retarded by a diarrhœa of long standing, which he attributes to specific disease of the intestines, for which he is giving iodide of potash. He has never heard of a surgeon being infected by syphilitic virus during the performance of ovariotomy, yet he did not see why such an untoward result might not happen; so, during and after the operation, he was careful to cleanse his hands thoroughly and separately with a sublimate solution. Indeed, for several days after the operation, he was quite uneasy about himself, lest he had been inoculated.

Dr. Goodell also showed the left ovary of a young girl, 22 years old, which he had removed and which had two pus-cavities in it. No history of peritonitis could be elicited, yet the pelvic cavity was crossed and recrossed with bands of adhesion as tense as fiddle-strings. Many of these pelvic bands and other close adhesions of the ovary proper had to be broken during the operation. The right ovary could not be discovered anywhere, although very careful search was made both by Dr. Goodell and Dr. W. L. Taylor; and although the pelvic floor was pushed up by the hand introduced into the vagina. A small body as large as a bean, which was possibly a rudimentary ovary, was felt in the right broad ligament; but it was so obscured by organized exudation and fastened down by adhesions, that no effort to remove it was deemed proper. All the pain was referred by the girl to the left ovary. Dr. Goodell thought that in this case the lesions had come from some exanthematous disease of childhood, or from latent peritonitis, just as adhesion-bands are often found in the pleura, when no history of pleurisy can be found. The girl in this case was a virgin, and he felt very confident that gonorrhœal infection could be excluded. Owing to a constant oozing of blood, the drainage-tube was kept in for eleven days, a rubber one being substituted for the glass one at the end of the first week. Not any complications have retarded her convalescence.

Dr. B. F. Baer presented a specimen of

Broad-Ligament Cyst,

removed by enucleation, which had been tapped seven times in seven years.

Miss A. was sent to him by his friend, Dr. S. S. Smith, of Driftwood, Pa., and entered

his private infirmary on Oct. 3. She is single; 44 years of age; had enjoyed good health until eight years ago, when she found that her abdomen was increasing in size. She also complained of a peculiar pain, "pulling down in the pelvis," as she called it. Her abdomen continued to increase in size, until she had such difficulty in breathing that she could not walk upstairs without suffering great dyspnœa. She was tapped on Aug. 2, 1882, and four gallons of fluid, "as clear as spring-water," were removed. She does not think that she lost any flesh during the early development of the tumor. In nine months she was tapped again, and three gallons of fluid removed. Between the first and second tappings she lost considerable flesh. At about the same interval she was tapped again, and three gallons of fluid removed. She was tapped yearly since Aug. 2, 1882—seven times in all—the last tapping occurring in April of this year.

Two or three years ago she began to flow more freely at her periods, until they became so profuse that she would flow as long as a month at a time. About the same time she noticed that there was a projection from the vulvar orifice which would become larger if she were on her feet and retained her water, and diminished in size after the bladder was empty. She presents an appearance of considerable emaciation, and states that she is rapidly losing strength. Inspection shows the abdomen to be symmetrically distended to the extent seen in the sixth month of gestation. The abdominal wall is very loose and flaccid. There is a circular scar midway between the umbilicus and pubes; and on questioning the patient, she explains that four years before she had a "running sore," which continued about two years. The suppuration followed one of the tappings and took place from the puncture. Palpation of the abdomen shows a loose thin-walled cyst in the cavity, which does not seem to be adherent to the abdominal wall; fluctuation is marked. Inspection of the vulvar orifice shows a cystocele, about the size of a duck's egg, and also an inflammatory swelling of the left labium majus. The vaginal touch shows the cervix to be near the orifice of the vagina, and to be quite small. The lower part of the tumor is felt very distinctly posteriorly, and low down in the pelvis. The uterus is pushed forward and to the right and occupies a position out of the pelvis above the right groin. The sound passes through the centre of the body last described to the depth of four inches, and shows it to be positively the uterus. The tumor appeared to have pelvic attachments below the uterus as though it might be an intra-ligamentous cyst

Operation October 6, in the presence of Drs. T. M. Drysdale and Charles P. Noble; and I was kindly assisted by Drs. J. M. Baldy and J. S. Baer. The incision was two inches in length. When the tumor was exposed to view it was found to be firmly adherent, in several places, to the anterior abdominal wall and to the point opposite the scar that was the seat of the former suppurating, fistulous opening; it was found that the fimbriated extremity of the Fallopian tube formed this latter attachment. It was this attachment of the extremity of the tube, which had probably caused the elevation of the womb, as that organ seemed to be suspended from the point noted—the Fallopian tube extending from this point downward over the tumor to the uterus, forming a portion of the wall of the tumor. It was also noticed that the outer and upper wall of the tumor was apparently closely adherent to the intestines—so closely indeed that it was necessary carefully to select a place where puncture could be made without wounding the bowel. About two gallons of thin fluid, rather straw-colored, was evacuated, when the cyst entirely collapsed. On attempting to draw it out it was found to be so deeply attached that it could not be withdrawn. The upper portion of the cyst wall seemed to consist entirely of the intestines, which escaped through the incision when traction was made upon the cyst. They were hurriedly returned, and the fingers carried downward toward the base of the tumor, when it was found that the entire pelvic peritoneum of the left side was lifted up—that is, the tumor was entirely subperitoneal and without a pedicle. A condition now presented itself which renders this case one of extreme interest. The base of the tumor was so broad, vascular and so closely attached to the intestines, that to have begun to enucleate below would have been hazardous on account of the danger of rupturing the bowel, as well as of hemorrhage, which would probably have been great from the opening of large blood-vessels. We determined that it would be best in this case to begin to enucleate at the point of puncture of the trocar; and it was found, much to our satisfaction, that the cyst was readily separated from its outer or peritoneal coat. So readily was this done that it was unnecessary to ligate a single blood-vessel, and the enucleation was finished within ten minutes. After the enucleation was com-

pleted, the entire peritoneal covering collapsed and disappeared. It contracted so quickly indeed as to make it difficult for me to find its cavity for the purpose of irrigation, which was next done. The thick Fallopian tube was next ligated and cut away; but the tumor itself was entirely without a pedicle, and was monocystic, as you will see in this beautiful specimen. After irrigating, the wound was closed around a small drainage-tube and the patient returned to bed, showing some evidence of shock from the operation, from which, however, she soon rallied. The drainage-tube was removed within 36 hours, and the patient has recovered. During the third and fourth days, the urine was found to contain pus and blood; but on investigation it was found that these probably originated from a former cystitis. The bladder was washed out twice daily with carbolized water, and she soon recovered from this condition.

In my experience this case is unique. The cases of broad-ligament cysts, requiring enucleation, with which I have met, have been of such character as to require the application of many ligatures and pressure forceps to control the hemorrhage during enucleation. Whether this is because I formerly began to enucleate near the base of the tumor, by breaking through the outer covering, or because it is seldom that we meet with a tumor so easily enucleated as this one was, I do not know; but I lean rather to the latter view. My experience with this case, however, will lead me to endeavor, in future, to begin the enucleation high up, at the top and less vascular part of the cyst wall. It was long ago pointed out by Bantock that in broad-ligament or par-ovarian cysts the peritoneal covering could be readily separated from the cyst proper. This served to distinguish it from the cyst of the ovary, the outer wall of which cannot be separated from the covering beneath it. While this was an intra-ligamentary cyst, it was not that form of cyst which is described by Doran as originating in the hilum of the ovary and containing papillary growths, several specimens of which I have exhibited to this Society.

Dr. B. C. Hirst showed an

Intra-Ligamentous Cyst.

This specimen was recently removed by an operation performed by Dr. T. H. Bradford, at which I had the pleasure of assisting. The tumor sprang from the right broad ligament and was attached deep down in the pelvis. Its blood-vessels were enormous. It was covered by that curious muscular-looking capsule which makes these tumors resemble an enlarged uterus. There was furious hemorrhage at the lower attachment, when an attempt was made to ligate the pedicle. This was only controlled by a long pair of catch-forceps passed in the dark. The entire tumor was removed and the stump cauterized. The operation lasted over three hours and the woman almost died on the table. She recovered from the immediate effects of the operation, but died three days later. The mass consists of a papillary growth internally, and a capsule which shows a feature referred to by Dr. Goodell at a meeting of the Society last December, and that is, the seeming rottenness of the tumor-wall in spots which makes it exceedingly difficult to remove these growths without tearing them and allowing some of their contents to escape into the peritoneal cavity. This happened in the present case. Had the woman lived, it is probable that the peritoneal surface would have been infected by this papillomatous matter.

In opening the discussion on the papers read, Dr. R. P. Harris mentioned the case of the late Dr. Emeline Cleveland who had become infected from an ovariotomy and had a syphilitic sore develop on her wrist, which ultimately was the cause of her death.

Dr. Joseph Price said the case reported by Dr. Goodell illustrated beautifully the primary and the secondary value of the tube—the signal of hemorrhage and the cure of the abscess which formed later. The woman would have perished from the hemorrhage or the abscess had the tube not been used. In regard to the virulence of living pus, he might say that he had twice been poisoned in abdominal work. Virchow had called attention, long since, to the virulence of living pus. He differed entirely from Dr. Baer as regarded the nature of the cyst which he had presented. It was clearly a par-ovarian cyst. It belonged to that class of tumors to which are applied the minor methods of treatment without knowing exactly what the tumor was. In this case the capsule may be stripped off, and a cyst still be left. This could have been done more readily if the specimen were a recent one. The other day, he removed an enormous par-ovarian cyst and in a few minutes was able to convert it into two cysts. Such tumors are always par-ovarian, and the enucleation is easy.

Dr. Baer said he had already separated

the two coats of the cyst. He would confess frankly that after reading Doran and other authors on this subject, he did not yet exactly understand the difference between these tumors.

Dr. Slocum asked Dr. Goodell what, in his opinion, was the origin of the two cysts in his case.

Dr. George E. Shoemaker thought that in using the bichloride solution to wash out incised and punctured wounds, that it did not penetrate deeply. He would hesitate to place dependence on it unless the wound was large enough for free irrigation, and unless the solution was strong. A solution made of alcohol and bichloride was the best, as the solution would penetrate to all depths. The bleeding should be encouraged and the wound should be enlarged.

Dr. H. A. Kelly thought that Dr. Baer had developed an interesting point in not using any ligatures. He had himself operated in four or five cases in which no tying was required. One of his cases was a pus-sac and a small ovarian cyst. After enucleating the mass, nothing but oozing points were left. He attributed this to the fact, to which he had before called attention, that after adhesions had formed, the original blood-source had withered away and the mass was supplied by blood from the surrounding parts. In the case of another cyst closely resembling this, he had to use a greater number of ligatures than he had ever before used. Every point seemed to bleed and required separate ligature. This case was drained, and the patient recovered after a pus-sac had been opened from the vagina. He now seldom used a drainage-tube—never where he could avoid it. He did not fear clean blood and clean fluid if not in too great quantity. He had had no trouble for a time in his hospital, since he had adopted this method.

Dr. J. M. Baldy called attention to a point mentioned by Dr. Baer, who had stated that the Fallopian tube was attached near the umbilicus at the point of a scar produced by one of the tapping punctures. This is another illustration of the dangers which all now realize. The tube had been perforated by the aspirator and had become attached to the abdominal wall near the umbilicus. It had here discharged pus for a long time. The fistula which had been left could not be accounted for until the operation. The result of this accident might easily have been most disastrous.

Dr. William Goodell remarked that in reply to the question what the other cysts were, he must confess that he could not explain them satisfactorily. Their presence was something new to him. Whether or not they were due to the syphilitic element he was unable to say. He knew that one was wholly independent of the other two cysts. He was not so sure of the second. He was disposed to attribute the abscess to one of these cysts taking on inflammatory action subsequently. With reference to the distinction between par-ovarian and broad-ligament cysts, he must confess that he had labored under the same difficulties that Dr. Baer had. The term broad-ligament cyst is a generic one, for there are differences in broad-ligament cysts. In a par-ovarian cyst the two layers can be readily stripped from one another. In an ovarian cyst, on the other hand, every escaping Graafian follicle has caused a scar which rivets the two tissues together, so that in such a cyst the two layers cannot be separated. Of broad-ligament cysts we have two typical varieties: one, the true intra-ligamentary cyst, usually containing papillary growths and attributed by Doran to the hilum of the ovary; the other, of which he thought Dr. Baer's specimen was an illustration, is a cyst starting from the horizontal or vertical tubes of the par-ovarium. These are very beautiful translucent cysts, over which the fimbriæ of the Fallopian tube run and spread like the fronds of sea-weed. They also contain a limpid fluid. A third broad-ligament cyst is the hydatid of Morgagni. There are other cysts to which Doran has referred, but he did not understand fully his description and he thought that Doran himself does not clearly understand them, from his description. Others describe other broad-ligament cysts. They assert that cysts will form here as elsewhere. For instance, we have retention cysts in the labia from enlargement of the glands of Duverney, and we have other cysts not connected with this gland. These are attributed by some to serous accumulations in the interspaces of areolar tissue. In order to simplify matters, he divides these cysts into two sets: the true par-ovarian cysts and the true intra-ligamentary cysts, liable to contain papilloma. These intra-ligamentary cysts try him more than any other kind; the deep and tedious enucleation and the spouting vessels beyond reach make anxious work. The adhesions also obscure the land-marks and are very perplexing. About five weeks ago he tackled one of these cysts, and in endeavoring to enucleate it he tore a hole in the bladder, into which three fingers could be

introduced. The same accident happened to him several years ago, before he had ever heard of an intra-ligamentary cyst. Both cases, fortunately, recovered. He sewed up the wound in the bladder, in this last case, with a continuous cat-gut suture. He then took the portion of broad ligament which had been stripped up and united that over the bladder, so that he had two sets of sutures, like the Czerny-Lembert suture in wounds of the intestine. He introduced a self-retaining catheter and there was no further trouble, except that the eyes of the instrument at first became clogged by the blood in the bladder. In the former case a good deal of blood accumulated in the bladder. This he was able to dislodge by injecting a solution of pepsine, which seemed to digest and break up the clots.

Reports of Clinics.

BELLEVUE HOSPITAL.

MEDICAL CLINIC—PROF. JANEWAY.

Hæmothorax.

Case I.—The patient was a man, 46 years old. His father died of phthisis, his mother of old age. His previous history is good; he has not had syphilis, but has had attacks of "cold" several times; he is a moderate drinker. His present trouble began three weeks ago, with pain in the left side of the chest, cough, and some shortness of breath. He has had since then, on several occasions, chills, fevers, and sweats. He has been in the Hospital only two days. His temperature has varied from 98°.6 to 100°¾; the pulse, from 70 to 104; the respirations, from 24 to 28. Yesterday (Nov. 1), while a physical examination of his chest was being made, he fell over in a clonic convulsion, during which he became pale. The convulsion lasted about five minutes. On questioning, the patient admits having suffered from somewhat similar attacks, which he calls "faintness," during the last twenty years. He would usually, he says, lose consciousness during them.

Examining the patient to-day, he is noticed to be markedly anæmic. This paleness he has himself observed for some months. The heart beat is indistinct; the cardiac dulness normal; there is a faint systolic murmur at the base, which is, in all probability, hæmic. On setting the patient up there is noticed some œdema of the back. By percussion, the right side is found to be flat from the angle of the scapula down. This line of flatness is at least three inches higher in the axillary line, but at the same level in front as behind. The respiratory murmur and voice are absent in this location. The line of flatness varies somewhat with the position of the patient. Above this line the respiratory murmur is good. During the last few days, the patient has complained of pain in the left side. Examination reveals, low down, a narrow area of flatness and loss of respiratory and vocal sounds. These physical signs in the left side were not present yesterday; and on the right side were one and one-half inches lower down. Examination of the urine gives negative results.

This patient, then, is suffering from an accumulation of fluid in the chest. To determine what it is, an aspirator-needle will be introduced. In the left side, no fluid is found; from the right side, some dark-colored, thick blood is withdrawn. It will be noticed that it is blood, and not bloody serum. This procedure was undertaken yesterday, and the House Physician tells me that this fluid, examined microscopically, is found filled with many red blood corpuscles; it contains no pus. This patient has hæmothorax. The question arises, had he pleurisy first, or had he the hemorrhage first and the inflammation secondarily? This cannot be decided positively, as the patient has not been under observation since the beginning, and the history is not clear.

Now, what is likely to have been the cause of the hæmothorax in this case? Very little upon this disease will be found in the text-books. We will therefore carefully go over the causes that may give rise to this affection, and apply them to this case. First among these, is a giving way of the lung, from hemorrhagic infarction, gangrene or abscess. Here we would expect to find pneumo-hydrothorax. We have seen, however, that this patient has a good respiratory murmur in the upper part of his chest; we can therefore exclude pneumothorax. Next, the cause might be traumatism. This is the most frequent cause of hæmothorax. By a careful questioning we are able to exclude this also: he has had no fall and no injury. Scurvy is another cause. The patient's gums are not ulcerated, and are healthy-looking; no purpuric spots are found on his body; this cause also can be excluded. Again, hemorrhage into the pleural cavity may occur from the giving way of a varicose

vein (which is very rare), or the giving way of an aneurism. These cases are likely to die at once; it is not at all probable, therefore, that the bleeding would occur as slowly as it has in this patient. Moreover, there are no signs of aneurism to be found along the spinal column by percussion or auscultation; and there is no bulging of the chest wall, as almost always takes place, and is indeed the chief sign. Another cause of pleural hemorrhage is tubercle or cancer. Tubercular pleurisy is especially liable to be hemorrhagic in a patient as anæmic as this one. There are no signs of phthisis, and no history of cancer. Hemorrhagic diathesis may also be excluded by the history of the patient. Still another cause of this condition is the rupture of a small vessel, possibly constricted, during a convulsion.

Dr. Janeway was inclined to consider the patient's fainting attacks as attacks of *petit mal.* The man denies that he has ever had convulsions or twitchings, or that he has ever bitten his tongue in these seizures; yet these fits of unconsciousness have occurred for as long as twenty years, and with more or less regularity and frequency. The cause of the hæmothorax in this instance is, of course, doubtful; Dr. Janeway inclined to the view that it proceeded from a rupture of a small vessel during a fit. The fact that yesterday he had such an attack, and to-day the amount of blood is increased, adds to the probability of this view.

Rheumatoid Arthritis—Gout.

Prof. Janeway next presented two patients illustrating the different appearances between rheumatoid arthritis and gout. Both were men; one was 27 years old, the other 65. One had been sick two years; the other thirty-four years. One had several joints of the hands red, swollen and still painful, and showing some considerable effusion (which may or may not take place in these cases), and in others partial anchylosis; the other patient had bird-claw hands and showed other joints swollen from hard deposits in them, and subluxated and movable. This patient also had deposits of urate of soda in the ears, along the tendons (principally in the leg) and under the skin in many locations. There was also characteristic crepitation in the knee, when that joint was moved. [This case of gout has improved during the past year. His deposits are less than they were. It might be interesting to know that he has taken, during this time, a diet of milk, eggs, and potatoes, and almost no meat.] Dr. Janeway called attention to the fact that rheumatic arthritis is to be distinguished from gout by the absence of gouty history and by the persistence of the disease. It remains in a joint after once attacking it, and later other joints may be involved in the same manner. Another point of distinction is the occurrence of anchylosis in the former.

Cirrhosis of Liver.

Case IV.—The patient was a man, 42 years old, a hard drinker: he has averaged a pint of whiskey daily for the last fifteen years. He has suffered from stomach symptoms for some years. Five years ago he had jaundice, which has persisted, more or less, up to the present time. He has now been sick in bed for two months. He grew emaciated, weak, had vomiting, and jaundice increased. He also had cough, with salty expectoration; but no fever and no sweats. His stools are yellow—not white. Be careful, said Dr. Janeway, in these cases, not to let the patient mix the feces with the urine; the urine being loaded with bile will stain the feces superficially. Have each passed in a separate vessel.

Examination reveals a fulness in the epigastrium and right hypochondrium, which swelling moves with the respiration and is of firm resistance. It has a sharp edge and two notches can be felt. By percussion, the upper limit is found about at the normal situation; the lower edge is four or five inches below the free border of the ribs. It feels smooth and is a uniform enlargement. The diagnosis is hypertrophic cirrhosis—not cancer and not waxy liver. The jaundice is not complete, and it comes and goes. There is no history of long suppuration, or other common cause of waxy liver, and some enlargement of the spleen is found—which is likely to accompany these cases of cirrhosis.

—Three cases of yellow fever are reported at Ellaville, Fla.

—A son of Dr. S. Fleet Spier, a prominent Brooklyn physician, was attacked by diphtheria some time ago, but recovered with careful nursing. His father took him, November 9, to the temporary headquarters of the Long Island Gun Club in New Suffolk. Two days later young Spier went out for a walk before breakfast. Half an hour later a boy brought word that he had seen a young man fall down in the road. Dr. Spier was quickly guided to the spot, where he found his son dead from an attack of heart disease.

Foreign Correspondence.

LETTER FROM BERLIN.

Primary Sarcoma of the Pancreas.—Phthisis of the Stomach.—Bacillus of Whooping-Cough.—Amputating the Wrong Leg.—Sir Morell Mackenzie and Prof. Bergmann.—University of Berlin.

BERLIN, Oct. 26, 1888.

A truly unique case—primary sarcoma of the pancreas, was presented this week to the *Verein für innere Medicin* by Dr. Litten. When the patient, a boy four years of age, was first examined by the physician, no symptoms could be elicited except some occasional relaxation of the bowels and pain on pressure in the abdomen. Two weeks later the boy presented an enormous emaciation, although his bodily weight had increased eight or ten pounds. The abdomen showed, even on superficial inspection, a well circumscribed tumor with hard borders and nodes. The rapid emaciation and enormous growth indicated a malignant neoplasm, the true character of which could not be defined during life, although it was taken for a cancer of the kidney, as this form of malignant growth is not infrequent in children. The boy died in a few days, and the autopsy revealed a cancerous growth of the pancreas, filling out the entire abdominal cavity. The tumor, on microscopic examination, was found to consist of small cells. The case is quite noteworthy, as no primary cancer of the pancreas has hitherto been described in medical literature.

At the same meeting, Dr. G. Meyer presented some rare pathological preparations, of which those showing phthisis of the stomach invited general attention. Meyer proposed this name for those conditions of the mucous membrane of the stomach which have hitherto been termed atrophy of the stomach. The specimens in question showed distinctly the transition from chronic inflammation of the mucous membrane to phthisical degeneration and the mucous infiltration of the glandular cells leading to phthisis of the pylorus.

Your correspondent has just perused an important study in the domain of bacteriological pathology, viz., the researches of Dr. Afanassiew on The Etiology and Clinical Bacteriology of Whooping-Cough. The results of this experimenter's labors are of vital significance, for there is no doubt that he has succeeded in isolating the specific bacillus of whooping-cough. The author's conclusions can be conveniently epitomized as follows: 1. The sputum of all patients affected with pertussis contains a fine, short bacillus, which differs from other microörganisms in morphological and biological respects. 2. This bacillus has a pathogenic character; for, by injections of it into the larynx or lungs of dogs, the symptoms of pertussis can be provoked. 3. The bacillus is found in the infected animals in the mucous membrane of the respiratory passages. 4. In children who die of pertussis the bacillus can be found in the lungs and in the mucous membrane of the respiratory passages. 5. The experimenter gives to this pathogenic microbe the name of *bacillus tussis convulsivæ*. Semtschenko, who has also studied the bacteriological etiology of pertussis, has come to the same conclusion as Afanassiew. The former observer found that the bacillus could be detected after the fourth day of the attack, and that it disappeared only with the cessation of the paroxysms. However important this discovery of the bacteriological cause of whooping-cough may be, there is but little probability that it will advance the therapeutics of the affection. Thus far, at least, bacteriological discoveries have been of but little practical utility in the treatment of diseases.

Another interesting pamphlet just out, is Surgical Mishaps, by Prof. Nussbaum, of Munich. It has often been asserted that the younger members of the profession especially could profit more by the publication of the failures in medicine and surgery, than by the publication of successes. Viewed from this point Nussbaum's paper will be a very welcome and useful novelty. Some mishaps which Nussbaum relates have a comical besides the necessarily tragical feature. He tells us, for instance, of the case of a peasant who, many years ago, was taken to the clinics of a great medical centre in order to be treated for multiple ulcers of both legs. On being examined on the operating table, the right leg was pronounced to be curable, while the left was declared to be incurable and to require amputation. The amputation had scarcely been performed when the surgeons found, to their great horror, that they had amputated the wrong leg! Their chagrin was still increased when the right leg, which by accident had been saved, healed in a short time spontaneously.

Speaking of surgical mishaps, the grave charges of Sir Morell Mackenzie against the German Professors who treated the late Emperor Frederick, naturally present them-

selves to our mind. To anyone who has seen some of the brilliant operations performed daily by Bergmann at the Royal Clinic in Berlin, it seems impossible that so experienced and skillful an operator could make such terrible blunders as are charged by Mackenzie. Many German physicians, who previously still sided with Mackenzie, have now decided against "the specialist," who, instead of defending himself scientifically, has flung absolutely incredible charges in the face of medical men of the highest authority. It is sincerely to be hoped that silence will now ensue in this unfortunate and lamentable case.

The Berlin University has again begun its great work, with over 6,000 students, nearly 5,000 of whom are "regular matriculates," *i. e.*, graduates of a classical high-school. Prof. Gerhardt, the great clinician, has just been invested with the insignia of the rectorship, the confirmation of Virchow's election to that office having been withheld by the Government. What small and contemptible policy it is to carry political strife into the sacred halls of science. Fortunately Virchow needs no offices, no orders, nor other royal favors; his name will go down to posterity as one of the greatest of medical scientists of all ages. The poet's *exegi monumentum ære perennius*, suits here admirably well. J. S.

LETTER FROM MELBOURNE.

(FROM OUR SPECIAL CORRESPONDENT.)

Clinical Instruction in Melbourne.—Hospital for Sick Children.—A Favorite Liniment.—Mistura Pertussi.—Fees for Dispensary Treatment.—Mixed Marriages.—Hygienic Treatment of Chorea.

MELBOURNE, Sept 20, 1888.

I have said that clinical teaching seemed to be below par in this city, and on investigation it proves to be in a most wretched condition; so, while we may regret our short terms of study in theory, we can be proud of our clinical work in America. This may account for the fact that, when it comes to real down-right work, the American reaches the goal, even if he was shot through college in two years. Our clinical teachers are respected the world over, and in any well-stocked physician's library here you can find the titles of many American authors.

The most popular institution in the town is the Melbourne Hospital for Sick Children. Its general appearance and internal arrangements are as good as can be expected from the conversion of a large private mansion into a hospital—a change never fully successful. The out-patient department has a separate building about fifty yards away from the main hospital. I found Dr. Cole, one of the resident physicians, in charge. This is a rich and valuable clinic, one of the best in town, yet rarely attended by a student. A nurse is employed to aid in bandaging, and in dressing wounds, just such work as our boys at home would delight in doing. This very fact shows in a strong light the condition of clinical medicine in Melbourne. Dr. Cole says that the University is trying to make it compulsory to attend this service, but so far nothing has been done. About six hundred children are treated here each week. Think of the waste of lessons which could here be learned. There is no attempt at classification, except what the Resident Physician does as the cases appear before him. He may assign them to the visiting doctors on different days. If some student could pass through the waiting-room before the clinic hour, and group the cases, much hard work would be taken from Dr. Cole. An ordinary tea-bell calls the waiting one to come in, and during my visit a stream of thirty cases poured in that door in the space of one hour—two minutes to a case: varus, hip joint disease, spinal trouble, chicken pox, scrofula in all its varieties, catarrhal affections, were included; but as nothing especially interesting presented itself, I picked up the hospital pharmacopœia. It proved to be different from the usual American hospital pharmacopœia in that it was arranged for quick prescribing, and that it did not harp on the economy strain. Well do many of us remember the days of dispensary work in Philadelphia, when, to get nearer quinine than sulphate of cinchonia, or to dream of a purge more costly than Epsom salt, was running amuck of "Boards"; and when the shadow of displeasure rested on the brow of the Resident when we were called before him to explain why we had done thus and so. In this Melbourne volume I found quinine, citrate of iron and quinine, all the oleates—in fact, no discrimination seems to be made by reason of cost. Nothing essentially new appeared in the form of the prescriptions, except perhaps the frequency with which eucalyptus oil is used in external preparations.

A favorite liniment is composed of equal parts oil of eucalyptus and olive oil. Dr. Cole speaks highly of the *Mistura Pertussi*,

which is made up of: ammonium bromide and chloral, of each one grain; belladonna juice and wine of ipecac, of each three minims; syrup of Tolu, twenty minims, and water to make a teaspoonful. The standard disease, so to speak, of both in and out departments is hip-joint disease. Thomas's splint is the favorite method of dressing. Plaster-jackets for spinal diseases; thermo-cautery for nævus; oleates for skin disease of many types—so the cases and the treatment went along, nothing especially new or striking. All I can hope to do in these lines is to satisfy the curiosity which we all have to know how things are done in other parts. The conveniences in the examining-room were most meagre. A tin basin of water stood on a common kitchen table, the only article of furniture in the room except one chair and a settee; this basin was used by the Doctor as a finger-bowl—he would dip the ends of his fingers in and then wipe them on a towel laid over his lap. In examining a case of eczema of the buttocks, the general appearance of which might indicate a specific origin, Dr. Cole assured me that, while syphilis played an important part in the diseases of children in the out-department, as it does in all lands, yet specific eczema in the hospital was one of the rarest of diseases; no explanation was given of this statement.

Now I can record a useful feature; each applicant for treatment must pay a shilling a week as long as he is under treatment in the out-ward. If absolute poverty exists, so that even this small fee can not be paid, the Committee will pass such, but only on proof that the person is unable to pay; and this must be on the basis of a recommendation of some house-holder who is acquainted with the applicant. Care is used that those who are able to pay shall not impose upon the charity of the hospital. I saw a patient turned away, and it was fully proved that the patient was quite able to go to a physi cian. The Committee meets once a week, and all new applicants must appear before this body, which decides as to their worthiness for charitable care. This takes the matter out of the hands of the attending physicians, and the too usual habit of abusing charitable work is done away with. The disgraceful system of making the clinic room the feeder for the private office can not be carried on to the same extent here as in America, and thus one of the complaints made against hospital work is removed. Nowhere in the world is there such a flagrant abuse of this very thing as in Philadelphia, and as it is a well-known fact to the profession here, it makes one feel a little unpleasant to have it brought up. I assure you I do all in my power to correct any wrong impressions that may be held concerning us. I tell them here that it is but natural for quacks to play upon the great reputation that Philadelphia has earned as being one of the great medical centres of the world.

After the hour had passed in the out-department of this children's hospital, Dr. Cole introduced me to his colleague, Dr. A. J. Wood, who at present has charge of the in-department. He and Dr. Cole alternate once in two months in the two departments, thus giving each a chance to have a change, besides being able to follow up any cases that may be desirable to study. This institution is aided quite substantially by the Government, and it is also a favorite object for the charity of the wealthy ladies. I noticed a number of wards bearing the name of some well-known Colonial lady, she having bought the ward, as it is called, giving what would be requisite to build and furnish the ward complete, which is generally estimated at five thousand pounds. This just permits the name of the donor being given to the ward; to secure a life-control, a further donation of at least the same amount is required. The walls of the different wards are adorned with pictures, a donation from someone; and here and there hand-painted tiles and terra-cotta pipes were noticed, the work of some young ladies of means and leisure who do this to amuse the poor little ones, and to make the wards as attractive as possible. We do not wonder at this; of all the charities, it would seem to be the one that cares for the child which would most appeal to the natural instincts of women. There are nine wards and seventy beds, sixty-two of which are at present occupied. In midsummer the place is full to overflowing, and for the same reason that I have given so often—a great prevalence of typhoid fever: often one-fourth of the cases are of this disease. Dr. Wood tells me that there seems to be a four-year cycle of typhoid fever; for every four years the demands for entrance of this class of disease are completely beyond the accommodation of the hospital. Among the cases there are a number of half-caste—white and Chinese. This mixture I am told is very frequent here, and on consulting Mr. Hayter, the Government statistician, I find that quite a number of Chinese have married white women in the Colonies. There are also

some illegitimate children of this kind. Hayter says that in the last twenty years three hundred and fifty marriages of this kind have taken place in the colony of Victoria alone; of these women one hundred and sixty were Victoria-born; fifty-three were born in some other Australian colony; English, Welsh, and Scotch women numbered seventy-one; Irish, twenty-five; United States and Germany must own each two; the rest are from various parts of the globe. Some quite nice-looking and young white girls have been found living as concubines with Chinamen in Melbourne; on reproaching them they answer: "White chaps black our eyes, get drunk, and treat us mean; Chinamen treat us very well, give us plenty to eat and wear, and we are satisfied."

Passing through the wards, nothing presented itself as especially of interest: there are any number of "hip" cases. It is a strange fact that a case of rickets has never been seen in the hospital, and it is said to be very rare in the Colonies. In one bed was a patient admitted the day before with convulsions, who now is found to have an apex pneumonia—a common start for this kind of pneumonia. There were a number of cases of chorea, and some of most violent type; the treatment is the usual one—arsenic, in some cases strychnia, in the majority, rest in bed, good food, massage, etc. The Doctor let slip the opinion that he had lost much of his earlier faith in medicines, and in this line of cases especially; cases put on the hygienic plan in the total he had found to do fully as well as those treated with medicines. To prove this, we went over the histories of a number of the cases; one of the worst cases that has been in the hospital for a long time recovered under massage and rest. The average length of time to effect cure by either method was six weeks. Of late a convalescent ward has been opened at Brighton, one of the sea-shore suburbs of Melbourne; it is a cottage fitted to answer the purposes. The rooms of the Hospital are large and very sunny, and a fine outlook is obtained on the beautiful Carlton Gardens just opposite. A point worthy of note is the fine-looking, healthy and very intelligent corps of nurses; the children seem to be in love with their attendants, which was a most pleasing sight, and aids to soften somewhat the feeling of great pity which possesses one on seeing these poor little ones afflicted with most dire complaints.

PERISCOPE.

Antipyrine Rashes.

At the meeting of the South-East Hants District Medical Society, October 11, 1888, Dr. C. C. Claremont read a paper on antipyrine rashes, in which he described two cases which had occurred in his practice during the course of enteric fever. In the first, ten doses of fifteen grains had been given in the course of ten days, when the eruption appeared. It came out simultaneously on the abdomen, thorax, back, and limbs in the form of papules, darker, larger, and more solid than the spots of enteric fever. There was a considerable resemblance to measles. The eruption developed into enormous erythematous blotches, with much infiltration, their vivid red color being removed by pressure, leaving faint yellow pigmentary discoloration. The rash began to subside on the sixth day, and on the tenth day was only represented by faint coppery maculæ, resembling an old syphilitic eruption. Antipyrine was omitted on the appearance of the eruption. In the second case, the drug had been given in fifteen-grain doses, generally twice a day, and omitted altogether for four days. The enteric exanthem had been unusually copious. On the twentieth day of the exhibition of the drug there was a papular erythematous rash on the extensor surfaces of the arms; this spread to the flexor surfaces, and also affected the calves. The antipyrine was omitted. On the fourth day the rash had almost gone, leaving only slight redness and desquamation. The patient had a relapse of fever, and was again treated with antipyrine without suffering from a return of the eruption. Dr. Claremont stated that antipyrine rash generally was of the papulo-erythematous type, and began on the extensor surfaces of the elbows and knees. It had been described in one case as commencing on the face, and in another as extending to the mucous membranes. Once vesicles had been present. Its most constant characters are its bilateral symmetry and its duration of about five days, irrespective of the continuance or withdrawal of the drug. The entire absence of subjective symptoms was exceptional. A scarlatiniform rash had been mentioned, but Dr. Claremont had been unable to ascertain that it was more than a transient flushing, such as is produced by belladonna.—*British Med. Journal*, Oct. 27, 1888.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.00**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE HEALTH OF PHILADELPHIA.

The study of the reports of Boards of Health is not always the easiest or most entertaining exercise of an inquiring mind; but if it were carried out systematically, it would supply instruction of no mean value. The statistics gathered in Philadelphia furnish an illustration of this fact, for they have more than once served to correct misapprehensions founded upon an illogical application of assumptions which are theoretically sound, but which are sometimes used with more zeal than discretion.

Not long since a strong effort was made, with motives partly humane and partly mercenary, to show that the water-supply of Philadelphia was prejudicial to the health of its inhabitants; and from time to time alarmists arise who with well or ill-meaning ardor exploit the danger of local conditions. To such persons the study of statistics must be peculiarly distasteful, for they usually appear to have neglected it altogether.

These remarks are suggested by an examination of the report of the Health Officer of Philadelphia for the week ending Saturday, October 27, in which some curious and interesting points may be noted. The first is that the deaths from the principal zymotic diseases number only twenty-seven, and that these include only eleven deaths from typhoid fever, eight from scarlet fever, one from diphtheria, and two from what are classed as "malarial fevers." It is singular to note also among them four deaths from "cholera infantum."

Another noteworthy feature of this report concerns the distribution of the deaths in reference to age. About one-third (121) occurred before the age of five years, about one-third (110) between the ages of five and fifty years, and about one-third between the ages of fifty and one hundred years. Nearly one-fourth (77) of the persons who died had lived over sixty years—precisely as many as those who died in the first year of life, and almost twice as many as those who died of consumption of the lungs.

These facts—which are not peculiar to the period under consideration—are both interesting and instructive, and they indicate that the prospect for long life and health is remarkably good in Philadelphia. The actual death-rate shows little compared to an analysis of the causes of death and the ages at which it occurs. In a city with a population estimated at over a million, a death-rate of 17.42 per thousand per annum places it at the very head of large cities in the whole world; and when these deaths

are found to be distributed so evenly between the extremes of infancy and old age it is utterly unreasonable to believe that there are here any conditions peculiarly prejudicial to life or health.

It would be interesting, we believe, to apply this method of study to the statistics of other large cities, and to investigate closely the causes of death and the ages at which it occurs, with a view to ascertaining the actual influence of conditions which are commonly believed to affect the health of their inhabitants. Such a method could not fail of furnishing more exact information than the more general consideration of death-rates which is so often adopted by those who discuss the important problems of public health.

THE CARE OF THE INSANE.

At a recent meeting of the Committee on Lunacy of the State Board of Charities of Pennsylvania, resolutions were passed urging a more general adoption of certain measures which have already proved useful in a number of the institutions for the care of the insane in this State. One of these measures is the appointment of women physicians to have charge of the female patients, which has proved so successful in the Philadelphia Hospital, and at Harrisburg and Norristown. The State Hospitals at Dixmont, Danville and Warren have not yet taken such a step; but it is hoped that they will do so before long.

The Committee also urges the Legislature to appropriate funds sufficient to provide for the erection of buildings to receive the chronic insane, imbeciles and dements in the State, so that there shall be no need for keeping any of these unfortunates in almshouses.

In regard to idiots and feeble-minded persons, the Committee recommends the erection of a suitable retreat, to supplement the work now done by the excellent private Training School at Elwyn, or that this school shall be enlarged at the cost of the State.

One of the most important recommendations of the Committee refers to the treatment of the criminal insane. Notwithstanding the fact that as long ago as 1875 the Legislature of Pennsylvania was asked to provide for the erection of a building in which the criminal insane might be confined and treated, this has never been done, and a large number of such persons are still confined in prisons or almshouses. Such a practice is neither humane nor judicious, and the Committee advises the erection of a building easily accessible from all parts of the State, to which may be committed all insane persons who have committed serious crimes, as well as persons charged with, or convicted of, such crimes who are believed to be feigning insanity, or whose condition requires the investigation of experts to determine the condition of their minds. These provisions cover all cases in which insanity develops or is feigned after the commission of serious crimes, during the period of a sentence to imprisonment; and they apply as long as the real or feigned insanity continues, even after the termination of any judicial sentence, unless the friends of the prisoner are able to care for him or her satisfactorily.

The last resolution of the Committee urges the Managers and Trustees of the State Hospitals for the Insane at Harrisburg, Dixmont, Danville and Warren to consider the propriety of restricting the duties of the Medical Superintendents to the professional care and treatment of the inmates, and taking from them the administrative functions which they have hitherto exercised.

All of these recommendations except the last meet with our hearty approval, and we think they need only to be stated, to secure the approbation of all who have given much thought to the management of the insane. As to the last, the case is not quite so clear. There is much to be said in favor of the opinion expressed by the Committee; and yet there is also much to be said in favor of keeping the administration of an institution

for the insane in the hands of a competent medical superintendent. Those who favor the former view usually cite the example of the Hospital at Norristown, to show what may be accomplished where the medical officers exercise only professional functions; while those who favor the latter view point to the good work done in all the other large institutions in Pennsylvania which are practically governed by the medical officers, and to the unfortunate developments at Morris Plains, New Jersey, where the other plan has been pursued.

For the present it is by no means clear that the medical officers of institutions for the insane are not the best persons to manage them altogether, or that the admirable results of the dual form of government which exists at Norristown would be sure to follow its substitution for that which is found at the other State Hospitals in Pennsylvania.

Whatever may be the opinion of our readers on this particular question, we trust they will give careful consideration to the recommendations we have cited, and endeavor to impress right views in regard to them upon their representatives in the Legislatures of the States in which they reside. The interests involved are not local, but are of as pressing importance to our readers in Maine, or California, or Texas as to those in any part of the world.

In regard to the last of the Committee's recommendations we would be glad to have some expression of opinion from any of our readers who have had experience in the treatment of the insane, to aid us and all of our readers in arriving at a wise conclusion as to its value.

EARLY SIGNS OF PREGNANCY.

There are probably very few physicians who have not at times felt the need for some trustworthy means of deciding upon the existence or absence of pregnancy at a time when if present it could not be far advanced, and when it is too soon to expect to hear the sounds of the fetal heart or to obtain the confirmation of *ballottement*. In this country Hegar's sign of pregnancy, which has been well described by Dr. A. K. Bond, in an article in the *Maryland Medical Journal*, in the early part of this year, has not received the attention it deserves, and American physicians have failed to appreciate, or at least to practice, Hegar's method.

This sign is to be determined by combined rectal and abdominal examination. It consists in the detection of an unusual softness, thinning, and yielding condition of the lower uterine segment—that is, of the part immediately above the insertion of the sacro-uterine ligaments. This condition of the part is perceptible whether the rest of the body of the uterus feels firm and hard, or soft and elastic. Even in the latter case it is always possible to compress the lower uterine segment, to draw it out to a certain degree with the fingers, and so to distinguish it from the part above it; while below, the cylindrical cervix of firmer consistence is felt distinctly coming off from it. The yielding and flaccid condition of the part may be so great that one may doubt whether there is any connection at all between the neck and the larger swelling in the abdomen or pelvis. This is especially true when pregnancy occurs in uteri with hypertrophic elongation of the cervix; and even laparotomy has been done under the mistaken idea that the pregnant corpus was a tumor, independent of the uterus. The condition referred to depends upon the fact that the lower uterine segment, as the thinnest part of the corpus, on account of pregnancy, becomes succulent, of looser texture, thinned and extremely elastic. According to Reine, "failure to find this, however, in no way excludes pregnancy, since it is easy to see that with marked chronic infarctio uteri (hyperplasia), pregnancy may exist without rendering this condition of the lower uterine segment very evident."

There is another useful sign of pregnancy which depends upon the well-known fact

that, in the first eight weeks of pregnancy, the principal enlargement of the uterus is in the antero-posterior diameter of its corpus, while the cervix undergoes scarcely any change, except a superficial softening at the external os. The direction of the enlargement of the body of the uterus causes it to project markedly from the cervix, especially in front. The shape of the whole uterus has been likened by Grandin to an old-fashioned fat-bellied jug. This striking relation between the corpus and cervix is readily distinguished by one moderately skillful in making the bimanual examination. A quite characteristic bogginess, softening, and compressibility of the lower uterine segment is also detected. This sensation is brought about by the effects of the physiological congestion of pregnancy upon the uterine tissues, and partly, also, by the fluid contents of the uterus.

The condition just described is an almost positive sign of pregnancy, especially if in addition there is marked fulness and pulsation of the vessels on both sides of the pelvis, without evidence of pelvic inflammation, and a more or less distinct purple hue of the vagina. It is reliable as early as the sixth or eighth week.

It would seem, theoretically, that this method of examination had one marked advantage over combined rectal and abdominal examination, for not only can the physical condition of the lower uterine segment increased mobility of the corpus be made and out nearly as well, but the striking jutting out of the corpus over the cervix is much greater in front than behind and therefore more easily detected through the vagina than through the rectum. Naturally the employment of both methods of examination would give more trustworthy information than either alone. This condition of the lower uterine segment was apparently known to Dr. Rosch as long ago as 1873, but he failed to appreciate fully the subject and only laid stress on the feeling of fluctuation to be obtained by bimanual examination.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

PHYSICIANS' INTERPRETER. IN FOUR LANGUAGES. SPECIALLY ARRANGED FOR DIAGNOSIS. By M. von V. 206 pages 5 x 2½ inches. Philadelphia: F. A. Davis, 1888. Price, $1.00.

This little pocket-book contains a large number of questions and answers in English, French, German and Italian, especially arranged in parallel columns and adapted to the needs of medical men in conferring with their patients. The work is well done and calculated to be of great service to those who wish to acquire familiarity with the phrases used in questioning patients. More than this, we believe it would be a great help in acquiring a vocabulary to be used in reading medical books, and that it would furnish an excellent basis for beginning a study of any one of the languages which it includes. For the convenience of those who use it, it contains a large number of blank leaves to receive written notes.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

149. An Examination of the Eyes of Fifty Cases of Chorea in Childhood. By G. E. De Schweinitz, M.D., Philadelphia. From the *New York Medical Journal*, June 23, 1888. 13 pages.

150. The Differentiation of Serous Iritis from Subacute Primary Glaucoma, with a Brief Outline of Treatment. By N. C. Steele, M.D., Chattanooga, Tenn. 6 pages.

151. Report of Progress in Medicine and Surgery. By John S. Hughson, M.D., Sumter, S. C. From the *Transactions of the South Carolina Medical Association*, 1888. 11 pages.

152. Report on the Progress of Genito-Urinary Surgery. Some Points in the Management of Urethral Stricture. The Specific Microbes of Gonorrhœa. By E. R. Palmer, M.D., Louisville, Ky. From the *Amer. Practitioner and News.* 37 pages.

153. Exophthalmic Goitre. By Augustus A. Eshner, M.D., Philadelphia. Prize Essay, Jefferson Medical College, 1888. 8 pages.

154. The Gradual Preparatory Treatment of the Complications of Urinary and Fecal Fistulæ in Women, etc. By Nathan Bozeman, M.D., New York. From the *Transactions of the Ninth International Med. Congress.* Vol. II. 44 pages.

155. Operative Interference in Early Extra-Uterine Pregnancy. By Michael O'Hara, M.D., Philadelphia From the *Transactions of the Ninth International Med. Congress.* Vol. II. 4 pages (not numbered).

149. Dr. De Schweinitz presents an exceedingly good report of a very thorough examination of the eyes of fifty children who had chorea, and appends to it the conclusions to which his study has led him. The one of these which will probably make the most impression upon general practitioners is that the relation of chorea to errors of refraction is not yet clearly determined. This does not, of course, militate against doing all that may be possible to correct such errors.

There is a good deal more in this pamphlet than what we have already said describes, and it is calculated to be very useful to all who wish to be well-informed on this interesting subject.

150. The motive of Dr. Steele's pamphlet may be found in his statement that "great numbers of eyes have become stone-blind forever, because the attending doctor mistook glaucoma for some other disease, such as neuralgia, iritis, erysipelas or cataract." From this he proceeds to describe, by text and tables of symptoms, how such an error of diagnosis may be avoided. The section on treatment is very brief, but sufficient to indicate what is best to be done in both the conditions under discussion.

151. Dr. Hughson's paper discusses a few points of medicine and surgery in which notable advances have been made during the last five years. Antipyrin, antifebrin, sparteine and strophanthus are the drugs discussed, and operations for stone and diseases of the appendix vermiformis are the surgical subjects treated of.

152. The points covered in Dr. Palmer's little pamphlet are too numerous to be mentioned; but he gives in a small space a great deal of interesting and instructive matter. It will be unusually interesting to those who do not care to go through elaborate treatises on these subjects, and would be very entertaining reading for odd moments in the busy doctor's day.

153. Dr. Eshner presents a summary of the present knowledge in regard to this curious disorder, citing the views of many of the best known writers on the subject. Like all other writers, he devotes more space to the study of its pathology than to that of its treatment. As to the latter, he finds that the best results seem to have been obtained by the application of electricity to the neck.

155. Dr. Bozeman's paper is a long and elaborate one, covering the subject indicated in that part of its title quoted above, and also those for which there is less room in our columns than on his title page, namely, the treatment of pyelitis by a new method, and the prevention of the evils of incontinency of urine by a new system of drainage The paper is very full and contains a large number of well executed illustrations. It is hardly necessary to recommend it to the notice of the readers of the REPORTER in view of the reputation of its author.

155. The title of Dr. O'Hara's paper is not correctly worded. It ought to be: "Early operative interference in extra-uterine pregnancy." It contains a rather rambling report of two cases which had come under his observation, in one of which laparotomy was successfully performed by Dr. W. H. Parish.

—St. Joseph's Hospital in Montreal was damaged November 15, to the extent of about $30,000.

CORRESPONDENCE.

Cure of a Malingerer.

TO THE EDITOR.

Sir: An article in the REPORTER of the 3d instant, entitled "A Cunning Malingerer," reminds me of a remarkable cure I made in a somewhat similar case. It occurred in 1863. A private in the regiment of which I was surgeon suddenly became very deaf. I was certain he was malingering, but I could never catch him. He was always on his guard. He informed me that his father and two brothers became deaf on reaching his age, and continued so, in spite of every effort. I invited the surgeon of another regiment to be present at my "sick call," and informed him in the presence of the deaf soldier, and in a very low tone of voice, that I should perform the French operation the next morning upon my patient. The surgeon asked: "Which operation?" I informed him I should take a rod of iron the size of a crow's quill, and, heating it to a white heat, bore it through from ear to ear; that if it did not kill him, it might help him. The next morning when he appeared at sick call, before I could speak to him, he said: "You will not have to perform any operation, for something *busted* in my head last night and I can hear as well as I ever could." The cure was complete.

Yours truly,

WM. A. SMITH, M.D.,

Late Surg. 47th Reg. N. Y. S. Vol.

Newark, N. J.,

Nov. 6, 1888.

Prickly Ash and Abortion.

TO THE EDITOR.

Sir: Enclosed please find check for $5.00 to pay for one year's subscription to the MEDICAL AND SURGICAL REPORTER. I have not been a subscriber very long, but am better pleased with the REPORTER than any journal I have taken or read, and would not like to be without it. I wish to inquire of you, or, through the columns of your journal, of the medical profession, if anyone has ever known of miscarriage or abortion being produced by fluid extract of xanthoxylum (Prickly Ash)? I can find no mention of any such action in U. S. Dispensatory. I have used the drug a great many times in chronic muscular rheumatism, with excellent results; but in a recent case abortion followed its use and I would like to find out if the drug had anything to do with the acci-

dent, so as to be on my guard in the future. Hoping you will excuse me for troubling you with this inquiry, I remain

Yours truly,

X. Y. Z.

Hollis, N. H.,
Nov. 5, 1888.

[There is no reason to believe that the Prickly Ash can produce abortion except it were given in doses large enough to cause very great gastro-intestinal irritation, and then only in consequence of this action.—Ed. REPORTER.]

NOTES AND COMMENTS.

Association of Acting Assistant Surgeons of the U. S. Army.

Those familiar with the Army Medical History of the frontier for the past twenty or thirty years will readily bear witness to the faithful and intelligent discharge of their duties, by the Acting Assistant Surgeons of the U S. A. In fort and in camp, on the long overland expedition, or in the Indian wars, these men have done their duty as faithfully and with the same professional efficacy as if they had been regularly commissioned officers. Indeed, if they have not borne the burden and heat of the day, certainly their honorable records deserve recognition and preservation.

An association of past and present Acting Assistant Surgeons of the United States Army has been formed for the purpose of securing, so far as possible, a correct history of those who have served in this capacity, and also for mutual protection and benefit.

The Association desires to obtain a complete list of all medical men who have served as Acting Assistant Surgeons in the United States Army, and, so far as possible, their complete medical history, date and place of birth, date and place of graduation, date of appointment, medical service and stations, list of contributions to medical literature, inventions, etc., date of termination of service, professional positions held in civil life, present residence and address.

All information from friends concerning deceased A. A. Surgeons will be gratefully received. All past and present Acting Assistant Surgeons are cordially invited to become members of the Association. The badge of the Association is the Geneva Red Cross. The enrollment fee is $1.00. The necessary blanks will be forwarded upon application to W. Thornton Parker, M.D., Recorder A. A. A. S., Newport, R. I.

Disease in Adults and in Children.

Dr. W. H. Dickinson, in his introductory lecture on the differences between children and adults in regard to morbid action and the effects of treatment (*Lancet*, Nov. 3, 1888), says that such of their diseases as are of the nature of growths partake of the rate of progress which belongs to the period of development. This applies to the fibroses as well as to isolated tumors, though the fibroses are far more infrequent than afterward. Many inflammatory disorders, especially of the brain, are more common in childhood than later; but with regard to many inflammations, the power of recovery is greater. Inflammations of the lungs are more frequent and cause more deaths, but in the individual the prospect is better. Acute rheumatism is comparatively infrequent, but when it occurs it brings greater danger to the heart. Some febrile complaints are more frequent, and some less so, than afterward; but as a rule their proportionate mortality is less. There are special differences in the action of drugs, the most important of which is the greater influence of alcohol for good and evil. Finally, children respond to treatment — as they often succumb to disease — more readily than do older patients; so that with them our responsibility is greater.

Ice-Cream Poisoning.

The following particulars of a case of ice-cream poisoning which recently occurred at Mountain View, Santa Clara County, Cal., by which a number of persons were seriously affected, have been furnished by Dr. C. V. Jones of that town. The ice-cream freezer was a new one, being used for the first time, and had been constructed by the local tinsmith. It was made of tin, soldered on the inside to avoid cracks or crevices. The maker states that he has made over 100 in this manner and has so far had no complaint. A solution of zinc in muriatic acid is used in the soldering process, but this is readily removed by a thorough washing, which the person who made the ice-cream states that she gave the apparatus. The party, to the number of twenty, including the woman who made the ice-cream, were seized, soon after eating, with vomiting and purging, accompanied by severe griping pains. The vomited matter was noticed to be intensely acid. Under appropriate treatment the symptoms subsided, all the victims recovering within twenty-four hours.—*Sacramento Med. Times*, Nov., 1888.

Rectal Injections of Saline Fluids in place of Transfusion.

Mr. Rainsford F. Gill, in a clinical note to the *Lancet*, Nov. 3, 1888, says that he feels sure that the following method of treatment in severe cases of post-partum hemorrhage may be instrumental in saving life. It consists in the substitution of rectal injections of saline solution in place of transfusion, or rather, in those cases in which the performance of transfusion is impossible from want of the necessary apparatus. He is convinced that it proved efficacious in a case to which he was called a short time ago, and in which, on arrival, he found that the patient had lost an enormous quantity of blood and was delirious, with vomiting, etc., so that nothing could be retained. Before he succeeded in stopping the hemorrhage she was in a very collapsed condition, and on pouring a teaspoonful of fluid down her throat it was immediately rejected. He then used rectal injections, which were rapidly absorbed, so that within two hours she was again conscious and able to retain fluids given by the mouth. He thinks that if he had not used the injections in this case he would have lost the patient; and that it is precisely in such cases, in which the practitioner is without a transfusion apparatus, that the rectal injections are so useful, as he will always be provided with the syringe. Only two or three ounces of fluid should be injected at a time, and the injection repeated every ten or fifteen minutes, using a tepid solution; of course all auxiliary methods of relieving the existing shock to the system should also be employed.

The Southern Surgical and Gynecological Association.

The annual meeting of the Southern Surgical and Gynecological Association for this year will be held December 4, 5 and 6, at Birmingham, Alabama. The programme contains the titles of a large number of papers on important subjects in general and gynecological surgery, by men very well known in the profession.

Excursion rates to and from the meeting-place have been secured by the Committee of Arrangements, and those who desire to take advantage of them must obtain a certificate from the railroad agent on purchasing a ticket for Birmingham.

Further information may be obtained on application to Dr. J. D. S. Davis, Chairman Committee of Arrangements, Birmingham, Alabama.

NEWS.

—The University of Berlin is to have an additional Anatomical Institute.

—A Dental School is to be established in connection with the University of Vienna.

—All prescriptions in Alsace-Loraine must now be written in either German or Latin. The use of French for this purpose has been prohibited.

—Dr. Henry Miller, who made $3,000,000 in the manufacture of pills, was buried at Wilmington, Mass., recently. Large sums of money were spent upon the funeral.

—Dr. Edwin B. Shaw (*Kansas City Med. Index*, Oct., 1888) suggests the employment of rectal injection of hydrogen gas as a method of treatment of intussusception.

—The *Ledger* is responsible for the story that a Kalamazoo girl was engaged in a public gum-chewing contest at Minneapolis, and after an exhibition of rapid chewing her jaws "set." She rushed off to a physician, who discovered that some of the muscles of her jaw were paralyzed. In a short time the trouble passed away.

—During the year 1887, says the *Medical Press and Circular*, Nov. 7, 1888, there were 7,570 suicides in France. 2,168 were caused by cerebral affections; 1,528 by physical suffering; 202 were committed to avoid legal troubles; 800 were caused by alcoholism; 483 by poverty; 227 by disappointments in love, etc.

—Joseph Stewart, a colored man who practises medicine in this city, was ordered to stop posing as a doctor by Coroner Ashbridge, at an inquest held Nov. 16, on the death of a young white man, of consumption, at Stewart's house, where he had been about a month. Stewart is not a graduate of any college, and the Coroner ordered him to take his sign down and call in all his cards, otherwise he would report the facts to the District Attorney.

—Typhoid fever is said to be prevalent in many homes in the neighborhood of Montrose, the northern section of the village of South Orange, N. J., and several deaths have occurred. It is feared that others will succumb to the fever, which is spoken of as malignant. The circumstances connected with its appearance are of such a nature as to suggest that the disease is propagated by impure milk, which, being widely consumed, has led to the dissemination of the fever.

—A report has been made to the Central Board of Health of Melbourne, says the *British Med. Journal*, Nov. 3, 1888, describing an outbreak of diphtheria, the cases occurring almost simultaneously in the neighborhood of Daylesford. One child died, but the others are progressing favorably. The local health-officer has furnished a report pointing out the strong *primâ-facie* evidence that the children contracted the disease from cats, numbers of which are said to be dying in the neighborhood.

—The *News* and the *Journal* of Chicago still continue their war against cigarettes. The *News* has had a number of cigarettes of popular brands analyzed. They were stripped of every distinguishing mark, each brand put in a separate box, the lid of which was inscribed with a letter, and the whole lot then handed over to a well-known chemist. He found that the cigarettes submitted were generally made of tobacco "imperfectly fermented," and that nearly all had an unnatural proportion of insoluble ash; that several kinds were steeped in an injurious substance, and were impregnated with dirt in varying proportions.

HUMOR.

To be Developed Later.—"So your old uncle is dead, Charley?" "Yes, died yesterday." "He was a very eccentric old fellow. Do you think he was altogether right in his head?" "Well—er—I couldn't say, you know, until the will is read."

The Coachman's Diagnosis.—Gentleman, to the doctor's driver: "Tell me, how is the Councillor getting along?" Driver: "Oh, we've got him well; but the General is doing badly; we're having a great deal of trouble with him."—*Fliegende Blätter.*

Something Peculiar.—A. "My cousin is a queer fellow. I never know what he will do next; but it is always something peculiar." B. "For example?" A. "Well, just think, in the summer of 1888, the fellow got himself sun-struck!"—*Fliegende Blätter.*

A Remarkable Remedy.—"Doctor, I can't take this medicine; it tastes horrible!" "Oh, never mind, I have the most extraordinary results from this drug. I prescribe it for all my patients. None of them take it; and they all get well!"—*Fliegende Blätter.*

Loyal to the Last.—Husband (returning from the mountains)—"Are you chilly, my dear?" Wife—"I'm nearly frozen, John. Who was that gentleman in the straw hat and linen duster who just drove by?" Husband—"The landlord of the hotel below here."

Forgot About It.—Brown—"Have you seen Robinson recently, Dumley? I hear he has been sick." Dumley—"Yes, I saw him this morning." Brown—"How is he?" Dumley—"By thunder, I forgot to ask him. I just said 'How are you, old man?' and passed on."—*Time.*

For Value Received.—A correspondent writes to the *Cincinnati Lancet-Clinic*, October 6, 1888, that he on one occasion went to a meeting in which the pastor called on the old family physician of the neighborhood to offer prayer. The latter arose, and after an invocation of several minutes' duration ended his petition with this remarkable appeal: "And now, oh Lord, please be adoin' better by us in the future than you've been adoin' in the past, and then to you will be the power, glory, and everlastin' singin'. Amen."

OBITUARY.

HENRY B. SANDS, M.D.

Dr. Henry B. Sands, the eminent New York surgeon, died of heart-failure in a carriage on Fifth Avenue, Nov. 18, 1888. Dr. Sands was born September 27, 1830, in New York City, and made his home in that city and Brooklyn. On entering the College of Physicians and Surgeons of New York, he became known as a faithful and energetic student. He was graduated from the College in 1854, and immediately was offered a position in Bellevue Hospital. He subsequently went abroad to continue his studies. On his return, in 1857, he was made Demonstrator of Anatomy in the College of Physicians and Surgeons. During the past twenty-five years, he has been connected with many hospitals in New York City. His last position was Visiting Surgeon at Roosevelt Hospital, from which he resigned only last spring. Dr. Sands was frequently called in consultation in critical cases. When General Grant was suffering from cancer, Dr. Sands was called to consult regarding the advisability of an operation to remove a portion of the cancerous growth. With Dr. Barker he also had charge of Roscoe Conkling, and performed the surgical operation necessary. He is said to have been most successful in the operation of laparotomy.

CHARLES W. DULLES, M.D.

EDITOR AND PUBLISHER,

N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SOLUTION FERROUS MALATE.

(Amer. Phar. M'f'g Co.) 4 Grs. to Fluid Drachm.

DOSE —30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat, and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

Solution-Salicylate of Iron

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful four times a day.

An unfailing remedy in acute or chronic Rheumatism, where deformity has not yet resulted. Has also been prescribed with great satisfaction in other affections where Salicylic Acid, Bi-carb. Sodium and Ferrous Malate are indicated.

Ferrous Malate, Gentian & Cinchona

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

FOR THE INSANE.

CINCINNATI SANITARIUM.

PRIVATE HOSPITAL AND RESIDENCE.

(Incorporated 1873.)

Proprietary Interest Strictly Unprofessional.

Both sexes and all classes of mental and nervous diseases provided for.

Forty minutes by rail from C. H. & D. depot, Cincinnati. Address,

ORPHEUS EVERTS, M.D., Sup't.

COLLEGE HILL, OHIO.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

TREATMENT OF INSOMNIA BY HYPNOTISM.

BY ARTHUR C. HUGENSCHMIDT, M.D.
(UNIV. PA.), PARIS, FRANCE.

The remarkably refractory character of certain insomnias to the action of the numerous drugs that are recommended for them is well known. The three following cases, the only ones in which I have tried mental suggestion, have proved to me that hypnotism can be of great value in insomnia.

Case I.—A woman, 49 years old, who had been under medical treatment for several years, for well-advanced Bright's disease, complained especially of pain in different parts of her body. She had headache, pain in the chest, in the lumbar region, and down both thighs; she had been unable to sleep quietly for the past fifteen months. She was obliged to sit up in bed, while resting, on account of very severe coughing spells during the night, which often brought on vomiting. She suffered with renal asthma, the spells often coming on every ten minutes or quarter of an hour. She applied to me in May last, for relief especially against the insomnia, which had resisted all the drugs usually employed for this affection. I proposed to her to try hypnotism, and she readily assented.

I hypnotized her in less than five minutes at the first sitting, by making her fix her eyes upon the end of my index finger. As soon as she was asleep, I suggested to her the disappearance of all her pains, naming the different locations one after the other. I also said that she would have no more coughing spells during the night, and that she would sleep perfectly well and continuously during the whole night. I repeated this last phrase three or four times, to make a strong impression on her mind. The next day, she declared that she had had a continuous sleep during the night, had been able for the first time to lie flat on her back, and had had no coughing spell at all. She has felt much better ever since, and now sleeps very well; the pains also have disappeared. I learned subsequently that she now had occasionally coughing spells on awaking in the morning. At her next visit I shall again hypnotize her for this trouble, and for the pains in other locations which have appeared.

Case II.—A young woman, 26 years old, who had been nursing for over two months a younger sister suffering with scarlet fever and complications. As a result she had lost her sleep, which failed to be restored by all the hypnotic remedies used. I proposed to her parents the use of hypnotism, to which they assented. I made her fix her eyes upon my index finger, but I did not succeed in placing her in the proper position. The next day I tried again, with success this time. I suggested to her to sleep continuously that same night, and to awake only at the time at which she usually rose. That same night she had one continuous sleep, and has slept perfectly well ever since. At the time of this report, nine months have elapsed since she was hypnotized.

Case III.—A woman, 40 years old, who had lost her power to sleep, from nervous exhaustion and mental worry. She was less easily affected than the two patients just mentioned. I never could get a favorable

state for making my suggestion. Still, I obtained for her the first night four hours of continuous sleep; and having renewed the treatment several days in succession, I obtained six hours' sleep every night. I have not heard of this patient since she left Paris, the day following my last visit, and hence cannot say whether the result has been maintained or not.

Hypnotism certainly deserves to be faithfully tried, for I am confident that much good can be derived from its careful use in medicine. Whenever one or several drugs fail to produce the desired effect in a certain disease, give hypnotism a fair trial, and you will probably be repaid for your efforts. As to danger from its use, I have studied this method carefully for several years and employed it in many cases, without meeting with one single annoyance. I have used it, daily in one case, for over six months, without any apparent trouble. Professor Bernheim, of Nancy, has recorded one case in which he had hypnotized a patient daily for over two years, without noticing the slightest change in the intellectual state of his patient.

NASAL POLYPI.

BY BALDWIN GLEASON, M.D.,
PHILADELPHIA.

In the MEDICAL AND SURGICAL REPORTER, September 8, 1888, appeared a scholarly article by Dr. G. Archie Stockwell, upon "Nasal Polypi." Some of the statements in this article are so contrary to the experience of specialists in this city, that it seems hardly best to let the matter rest without a word of friendly criticism. The treatment, also, which he advised the general practitioner to use for the removal of these neoplasms, is so capable of doing great harm, unless used with extreme caution, that a word of warning will certainly not be out of place.

Dr. Stockwell states: "Papillomata, enchondromata, osteomata, and other tumors, are exceedingly rare, and consequently do not need to be considered in this connection." If by enchondromata and osteomata are meant cartilaginous and bony spurs and ridges, projecting from the septum into the breathing space of the nostril (the ecchondroses and exostoses of Seiler), then my experience has been just the reverse of his. It is probable that some such growths are present in the noses of at least one-third of those patients who apply to our dispensaries for the treatment of nasal catarrh. A certain number of such cases absolutely require the removal of the ecchondrosis or exostosis to bring about a cure of the catarrh or middle ear disease produced by their presence. During the past year, at least twenty such operations have been done, to every one for nasal polypi, in the Nose and Throat Dispensary of the University of Pennsylvania, and in the Nose and Throat Department of the Union Dispensary.

Among the causes of nasal polypi, given in Dr. Stockwell's paper, the theory of Dr. Woakes, of London, England, is conspicuous by its absence; and yet Dr. Woakes's theory will account for the presence of nasal polypi in three out of every four cases. This theory is briefly as follows: The two upper turbinated bones, with the nasal part of the ethmoid, are covered with "*muco-periosteum*," which dips into its spongy structure. When chronic inflammation of the muco-periosteum of the ethmoid extends to the periosteal strata of the membrane, a local "*necrosing ethmoiditis*" is set up. It is to the presence and irritation of necrosed spicules of bone, Dr. Woakes asserts, that the enormous proliferation of the soft tissues about the ethmoid, which we call polypi, are due.

In most cases after the removal of polypi, it is certainly possible to detect with a probe roughened and exposed bone. In some instances the disease will be found involving not only the middle turbinated body, but the cells of the ethmoid behind it as well. That necrosing ethmoiditis frequently exists without producing polypi, and plays its part as a cause of "catarrh" and various reflex symptoms, admits of proof; for there is frequently seen in our dispensaries the crater-shaped cleft of the middle turbinated body produced by the exfoliation of necrosed bone. In his work on Nasal Polypi, Dr. Woakes gives several drawings of such clefts in middle turbinated bones.

Dr. Stockwell states: "The connection between nasal polypi and asthma is oftentimes very intimate, as has been ably demonstrated by Voltolini and Joal; indeed, the latter is not unfrequently wholly dependent upon the former." The truth seems to be that any pressure upon the septal nerve is liable to produce asthma. Especially is this the case when both middle turbinated bones are enlarged so as to nip the septum between them. When the asthma is the result of a polypus, it usually occurs before anything more than polypoid degeneration of the mucous membrane covering the middle turbinated bone can

be discerned by the most careful examination. As the polypus grows, it finally escapes from between the middle turbinated bone and the septum. Its weight stretches the mucous membrane of the middle turbinated body, so that the pressure is partly or entirely removed from the septal nerve, and the asthma is not as troublesome. The removal of the polypus, under such circumstances, does not cure the asthma, but may, at least temporarily, make it worse.

The following case illustrates these points. Isaac B., 71 years old, came to the Nose and Throat Dispensary of the University Hospital complaining that he could not breathe through his left nostril. He had had asthma for fifteen years, but had been better for some years past. Examination showed a large, somewhat fibrous polypus, which had enlarged, but completely occluded, the left nostril. It was easily removed by the snare, and the wound healed rapidly under the use of antiseptic washes and applications. The mucous membrane of both middle turbinated bones was hypertrophied and pressed upon the septum, from which, however, it could be readily separated with a probe. The asthma, instead of being cured by the removal of the polypus, was so much worse that the patient could not sleep at night. Some hypertrophied mucous membrane was therefore removed with Farnham's alligator forceps, and the electro-cautery applied to the middle turbinated bone of the left side. Three days afterward, the patient reported that he had had no asthma since the last operation. Slight attacks of asthma afterward did occur, however, and the electro-cautery was then applied to the hypertrophied mucous membrane of the right side. Since the latter was done, some six months ago, there has been no asthma whatsoever; and the reflex chronic laryngitis, from which the old man suffered, has also disappeared, almost without treatment. It was not the removal of the polypus, therefore, which brought about this good result. Had no subsequent treatment been instituted, although the polypus might not have returned —for no necrosed bone was discovered, and the mucous membrane of the left middle turbinated body, while hypertrophied, was apparently healthy—yet the asthma would have remained uncured.

Dr. Stockwell advises, for the removal of nasal polypi by the general practitioner, a saturated solution of chromic acid, or the moistened crystals applied on cotton. Chromic acid is looked upon as dangerous when applied inside the nose, because it is exceedingly liable to spread upon adjacent parts and do great mischief. Many specialists, among whom is Dr. Seiler, refuse to use it at all, because it is so treacherous, and because there are so many safer escharotics, of which perhaps the galvano-cautery stands first. Those who use chromic acid at all, employ extreme caution; the method generally adopted is to fuse a minute quantity on the end of a probe and touch the spot where it is required, as recommended by Dr. Bosworth, of New York. Even when so used, some have had cause to regret it. It is difficult to neutralize it, and, if carbonate of potassa is used, a corrosive salt is the result. Workmen in chromate of potash works acquire perforation of the septum, sometimes after only a few weeks' exposure, so destructive is the action of even a minute quantity of the inhaled dust upon the cartilage of the septum. In the suburbs of our city lives a man with a perforated septum, the result of the application of chromic acid to an anterior hypertrophy by one of our specialists.

It would seem best for the general practitioner who feels himself obliged to operate on nasal polypi, to employ some safer weapon than chromic acid. Of these, probably the best is a reliable Jarvis snare, loaded with No. 4 or 5 imported piano-wire; for, however skilfully done, the operation with the forceps is bloody, brutal, and more difficult and painful than that with the snare. To remove polypi by Dr. Stockwell's method, the general practitioner must first provide himself with a concave head-mirror and a speculum—that of Bosworth is probably best, because it is self-retaining. A Jarvis snare will add but little to his expense for instruments. In using this, a lighted lamp should be placed at the right hand side of the patient's head, with the blaze on a level with, and slightly back of, his ear. Then the light is reflected from the head-mirror into the nostril dilated with the speculum; and finally, the size, number, and if possible the attachment of the polypi determined by means of inspection as well as palpation with a probe. Before using the probe, it is best to anæsthetize the mucous membrane of the nose by placing a pledget of cotton saturated with a four per cent. solution of cocaine in the nostrils, for two reasons: First, to prevent pain and sneezing, which might be produced by the gentle manipulations of the probe or wire loop; and second, because the cocaine contracts the turbinated tissues and thus, by enlarging the space, enables the examiner to see higher up into the anterior nasal cavities (Bosworth).

No difficulty will now be found in snaring off the polypi, without pain or the loss of more than a few drops of blood. Yet Dr. Stockwell states: "The introduction of the loop . . . is productive of more or less pain; and, after adjustment, the suffering produced by tightening and the process of removal is sufficient to prevent the patient undergoing a second torture usually necessary to clear wholly the nasal passages of morbid growths." All I can say to this is that either Dr. Stockwell has not a properly constructed Jarvis snare, or he has not mastered its manipulation; because it is the experience of most rhinologists that patients not only do not complain of the use of the snare, but express their delight at the painless and speedy manner in which the polypi are removed. It is not an uncommon thing for patients to request the continuance of the operation until both nasal cavities are clear of the obstructions; and as many as twenty-five or thirty of these neoplasms have been removed from one patient at a single sitting—a feat which it would be impossible to perform if the operation were as painful as Dr. Stockwell would have us believe. Then he tells us that it requires from a few hours to one or more days for a polypus to slough off after the application of chromic acid. In a case like the above, how many days or even weeks must be spent in doing, by Dr. Stockwell's method, what might be accomplished in a half-hour at the utmost, with the snare?

By whatsoever method the polypi have been removed, the patient should be seen at the end of a week. One of three conditions will be present: First, the wounds made by the removal of the polypi will be healed. If so, your work is done, if no other diseased condition of the nose requires your attention. Second, the removal of the lower polypi may have allowed one or more, which were wedged above the middle turbinated bone, to fall down where they can easily be seen and removed. Third, far more probably, however, an exceedingly tenacious muco-pus will be seen adhering to the middle turbinated bone. As this is removed with some difficulty, more exudes from minute openings. Introducing a delicate probe into such an opening, dead bone is discovered. Here, then, is present the condition described by Woakes. Perhaps cleavage exists, and the middle turbinated bone is divided into two parts by a crater-shaped opening from which dead bone has already been exfoliated. In this condition, manifestly, the task of curing the patient has only been begun by the removal of the polypi. Rest assured they will certainly return in a short time as long as spicules of dead bone are present to cause irritation. Treat the necrosing ethmoiditis as you would necrosis elsewhere. Remove little polypi as they sprout up, from time to time, with the snare or galvano-cautery. Try to assist nature to remove the spicules of necrosed bone by gently using the nasal curette, if they do not lie too deep. Order an antiseptic nose-wash, such as that made by dissolving Seiler's antiseptic tablets, for instance; make applications of suitable iodine preparations yourself once or twice a week. Sooner or later the spicula of necrosed bone will be exfoliated and the parts heal sound and well.

CONTINENCE: AN UNPOPULAR PROPHYLACTIC.

BY MADANA F. DE HART, M.D.,
JERSEY CITY, N. J.

The articles which have appeared in the REPORTER during the last year on the Conjugal Question, on Prostitution, and quite recently on the Prevention of Conception, have been full of interest, and they show that there is much in this subject which requires investigation before the profession can feel that they have settled these vexed questions; and when right theories are established, there will, no doubt, be a long interval before these ideal conditions can be realized, for some of these truths, when perceived, may require much self-denial for their practice, as the mistakes of former generations have, without doubt, diminished our ability to think correctly, or to keep our practice abreast of our knowledge.

It would seem that there must be something fundamentally and radically wrong in the practical relation of the sexes, as the many perplexing problems which refuse to be solved would seem to prove that we have failed to comprehend nature's intention and her laws.

History teaches that the same problems which confront the physician and moralist to-day, appeared in the earliest days. Thomas in his "Diseases of Women" tells us that the literature of Gynæcology commences with Hippocrates, who devoted three volumes to it, and that in the sixth century Ætius speaks of the speculum, sponge tents, medicated pessaries, vaginal

injections and dilatation of the contracted cervix, in such a manner as to leave no doubt as to his having a thorough knowledge of many disorders and means of investigation and treatment, which, being rediscovered thirteen centuries afterward, have, in many instances, been regarded by us as entirely new.

Lecky, in his History of Morals, tells us that monogamy was the general system of marriage in Greece, and says that nature, by making the number of males and females nearly equal, indicates it as natural; and that with no other form of marriage can the government of the family, which is one of the chief ends of marriage, be so happily sustained. He further says: "It is an undoubted truth that, however much moralists may enforce the obligation of extra-matrimonial purity, this obligation has never been even approximately regarded."

Physiologists give procreation as the sole function of the generative organs, but the present discussions on this subject would seem to imply that they had been diverted from their legitimate function. The attempt to subvert nature is always fraught with difficulties, and it is only when we are running parallel with natural laws that we have peace.

Darwin tells us, in his Descent of Man, that procreation is the sole function of the generative organs in all the lower animals, and that although the males fight among themselves until many of them are exterminated, for the much coveted privilege of possessing the female, *she* is never outraged—her wishes are a law never violated, and she seems to be allowed to choose between the survivors.

With what impropriety, then, do we sometimes compare the worst men to brutes, notwithstanding the fact that the latter seem able to keep their passions in entire subjection to the highest law they know—instinct?

Lecky, in his History of Rationalism, in speaking of witchcraft, says: "There are opinions that may be traced from age to age by footprints of blood, and the intensity of the suffering they caused is a measure of the intensity with which they were believed." It sometimes seems, in looking over the history of the race, that disaster has always followed close in the wake of the belief that men's passions must be gratified at any cost. One is sometimes moved to inquire what would be the effect of continence, as it is rarely mentioned as a cure for the evils which flow so surely from incontinence; although these are so great as to keep the world in a constant turmoil. It would seem as if the objections to it must be very formidable, in view of the fact that it is a perfect specific for so many of the evils which afflict society.

This would solve the problem of Population, which agitated Malthus, and continues to distract political economists of the present day; and it would seem, in the most natural way, without recourse to those unnatural means which are considered by many as both unhealthy and immoral. Children would then be born only of healthy, loving parents, able and willing to sacrifice and work for their good. Habits of self-control would be hereditary, and a few generations of such parentage could not fail to affect the race. Infanticide and fœticide, twin horrors which now sometimes drive unwilling and unhappy mothers to violate the strongest sentiment of their woman's nature—their love of offspring—would be prevented. Prostitution, that revolting blot on our civilization, with its thousands of victims doomed to lives of abject misery and early graves, would by these peaceful means be eradicated; and syphilis, that terrible scourge which is undermining the health of the nations, would soon be an unknown and almost forgotten horror. Diseases peculiar to women, of which we hear so much, would, without doubt, be greatly diminished, and women would look forward to maternity with joy rather than with terror, as they would be better able to bear its peculiar burdens if others were removed which render pregnancy and lactation so difficult. The fear of unfaithfulness on the part of their husbands during this trying period would be taken away, and their loving sympathy, which is so precious to wives at such times, could be enjoyed without exposing them to any injurious manifestations of passion, which so frequently cause nausea and vomiting, abortions and many nervous conditions which make pregnancy and parturition a season of deadly peril.

It may be said that this is simply impossible; but the first step in any reform is to establish an ideal and work toward it. Someone has said that the aspiration of our age is the code of the next. This must first be considered desirable; then, who shall limit the possibilities of heroic manhood? Can we claim to be the highest order of creation, if we fail to rule our lives by the highest faculties? and would men, in this ideal condition, sacrifice more for

fatherhood than women for motherhood? What better opportunity could be afforded them for the exercise of their physical and intellectual strength than this conquest over themselves, which might bring more good to the race than all their triumphs over material things as shown in railroads, telegraphs and steamships?

Anything which would prevent the misery caused by lust in this world would deserve to be ranked with that other reform of which we hear so much, "the abolition of poverty." When this millennium comes, female virtue will not be outraged and cannot be sold, as there will be no purchasers; then women will aspire to attract men by other means than an appeal to their lower natures, by merely physical charms. This will bring into exercise a higher order of faculties, as there will be an opportunity for their use, and the much lamented frivolity and weakness of intellect thought to be the distinguishing peculiarity of women will give place to the wisdom and goodness so urged upon them, by the precepts at least, of those who have found them too silly for intellectual companionship.

This reform would do away with the difference in the standards of morals for men and women, which is certainly an injury and injustice to both, as men need the moral support of a public sentiment which demands purity in them, and women would oftentimes be helped by one which did not insist that one mistake, for them, was fatal. There would be less occasion for unnatural stimulants if this drain on the vitality were removed, and we should avoid the injury to health and morals which a combination of intemperance and impurity entails, not only on the participants, but on their children's children.

With this array of good results, is this not a theory worth mentioning among so many that merely palliate evils which they cannot cure?

—A death attributed to carbolic acid poisoning occurred in this city Nov. 21.

—The *Harvard Crimson*, says the *Ledger*, Nov. 24, is authority for the statement that the Yale foot-ball player who had two teeth knocked out in the Yale-Pennsylvania game, replaced the teeth and held them in place with his tongue until the game was over, after which he sought a dentist, who tied them in with a silk thread. The cord has since been taken out, and the teeth are as firm as ever.

ACTION OF CARBONATE OF LIME AND BROMIDE OF ARSENIC.[1]

BY J. S. WIGHT, M.D.,
PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND COLLEGE HOSPITAL, BROOKLYN, N. Y.

I desire to describe briefly some observations I have made during the present year in regard to the action of certain remedies in the treatment of both inflammatory and non-inflammatory new formations: these remedies are carbonate of lime and bromide of arsenic. I have given them separately, as well as in conjunction. I have given the carbonate of lime with a bitter tonic before meals, and the bromide of arsenic after meals. The dose of the bromide of arsenic has been one-fortieth or one-twentieth of a grain. The dose of the carbonate of lime has been from five to twenty grains. Prepared as well as precipitated chalk has been used; but for the most part I have used prepared chalk. The results obtained by these two remedies in conjunction have been superior to the results following either when given without the other.

I have given these remedies in the following cases: 1. In different forms of inflammatory enlargement, some tending to suppuration, and some tending to induration. 2. In those enlargements that are on and near the boundary line between benign and malignant formations. 3. In those growths that have been called sarcoma and fibro-sarcoma, as well as adeno-sarcoma. 4. In cases of cancer. 5. I have also used them in the treatment of elephantiasis.

The leading idea in the therapeutics of these remedies is that they have more or less power to destroy morbific microbes; and I have given them on the theory that cancer, sarcoma and benign growths are caused by special microbes that act as irritants, producing specific proliferations. The specific proliferations and the special microbes together make up the mass of the so-called new growth. And I may add that I am more and more convinced that this theory may turn out to be true, when our knowledge has sufficiently advanced.

The results that I have up to the present obtained are very encouraging; in cases of inflammatory induration the improvement has been rapid and marked, as a rule. In some cases which have partaken of the

[1] Read before the Brooklyn Surgical Society, November 15, 1888.

nature of sarcoma, complete absorption has taken place in a few weeks. Cases of fibro-sarcoma have disappeared in a few months. One case of elephantiasis has been especially benefited by this plan of treatment, combined with the local use of mercuric chloride wash. Several cases of cancer in the last stage have been relieved, and the growth has been made slower. In one case of cancer the bromide of arsenic greatly lessened the pain for months. In another the local hemorrhages appeared to cease under its influence. In a case of cancer of the stomach the pain was much relieved and the appetite and digestion improved.

I have used other preparations of arsenic in the past, but, as far as I can now judge, the bromide of arsenic is the most desirable preparation. It has up to the present given me the best results. About two years ago I treated a patient for boils; my treatment was on general principles, and my patient did not get better. A man told me that he had known pulverized egg-shells to cure such a case. I tried the carbonate of lime, in the form of prepared chalk, and my patient recovered. Since that time I have extended the use of this remedy, and have found it to be valuable. One case of carbuncle in a woman of advanced years was made very mild by the use of carbonate of lime. I have given this remedy in two cases of diphtheria, which it appeared to arrest.

I am at the present time treating several patients with these remedies. Some of my professional friends are also using them. I am sufficiently impressed with their value to bring them before the Surgical Society, and suggest that they have a fair trial.

Let me add, with his permission, that Dr. Bates, of this city, has found a new microbe in cancer tissue, and has succeeded in cultivating it.

—"In a recent serious illness of a patient stopping in British Columbia," says the *Medical Record*, Nov. 24, 1888, "Sir Andrew Clark, of London, was consulted. Wires were arranged so that there was direct communication from London to New York, and thence to the patient. For three hours he examined and advised regarding his transatlantic patient's condition. This is a very remarkable achievement of modern science, but we should prefer a sensible and experienced physician near by to the most eminent doctor in the world five thousand miles away."

OUR HOSPITALS FOR THE INSANE POOR.

BY HIRAM CORSON, M.D.,
CONSHOHOCKEN, PA.

In response to the suggestion contained in the Editorial on the "Care of the Insane," in the REPORTER, November 24, 1888, I desire to lay before the readers of this journal some facts bearing upon the question proposed for discussion.

There are five hospitals in Pennsylvania for the care and treatment of the insane poor; four of which are managed in the same way—by a Superintendent, so called—a chief physician—with a Board of Trustees, the latter with scarcely a vestige of power to promote the success of the institution, though responsible for whatever of wrong-doing may be charged against it. There are the "Harrisburg Lunatic Hospital," organized in 1851; the Danville in 1862; the Warren in 1880—all State hospitals—and the Dixmont, at Pittsburg—not entirely owned by the State—in them Superintendents are appointed for ten years. The Eastern Hospital at Norristown is organized on a different plan. There are thirteen trustees, who are the governing power, and the chief physician has no other duties than those which pertain to his care and treatment of the insane as physician.

There has been an increasing dissatisfaction among thoughtful people, for several years, with the management of the four hospitals first named, and at the meeting of the State Medical Society in 1887 a preamble and resolution prepared by me were read by Dr. Samuel Wolfe, a delegate from Montgomery County Medical Society, which contained a brief statement of the changes believed to be necessary in the management of these four hospitals, and a request that a committee be appointed to memorialize the Legislature for such change in the laws governing them as would promote the welfare of the insane. I was unable to be at the meeting, and some strategy on the part of those who were opposed to any changes tending to diminish the power of the Superintendents prevented the consideration of the preamble and resolution.

At the meeting of the State Society held in Philadelphia in June last, I presented them again. The three Superintendents present immediately pounced upon me and gave me a pretty severe drubbing—and, as the time for adjournment had arrived, I had almost no time for reply, and a motion to

"lay on the table" was passed, and the matter closed. Afterward a committee of thirteen persons was appointed to investigate the management of all the hospitals and make report to the Legislature, and to the State Medical Society in 1889.

The Transactions of that meeting have been published and yet there is not a word of the preamble and resolution which caused such an exhibition of ill-feeling and coarse denunciation of the author, to be found in their pages. I will not stop here to inquire by what authority the Publishing Committee dropped them from the Transactions, especially as no more important subject was brought to the attention of the Society, nor any which caused more earnest discussion.

As every word of the preamble and resolution was true, it would seem to a person of common sense to have been a proper subject for fair, dispassionate discussion. Why was it not thus treated? Because for many years the physicians of Pennsylvania have given a silent acquiescence to the assumption, so industriously claimed, that none but Superintendents were qualified to judge of the needs of the insane, or to direct their management. Physicians ignored the subject, gave it over entirely to the Superintendents, and, like the latter, regarded every attempt to effect reforms, by anyone not officially connected with a hospital, as impertinent interference.

The opinions of persons who have yielded the care of the insane wholly to Superintendents who have been too much occupied by other duties than the medical care of the insane to give them proper attention, have not convinced me that I should at once give up all efforts for reform in management, and therefore I have interviewed many persons of acknowledged intelligence, some Senators and Representatives—our law-givers—to whom the appeal for change in the laws governing these hospitals must finally come, and, without a single exception, they have favored the proposed movement.

Inasmuch as the Publishing Committee by an unwarrantable assumption of power has excluded them from the Transactions, I desire to have them given to your readers. They are as follows:

"*Whereas*, In the State hospitals for the care and treatment of the insane poor at Harrisburg, Danville and Warren, the chief physician, under the name of Superintendent, has not only the care and medical treatment of hundreds of insane patients, but is also burdened with the entire control and management of the whole institution and the large farm connected with it, buying everything necessary for the daily consumption of the hundreds of inmates, the attendants and employés of every kind, hiring and discharging them as occasion may require—in a word, attending to every detail in management—duties far more than enough to occupy all his time, without giving a thought or a moment to the welfare of his patients, thus being compelled to leave them to the care of his young assistants, to the great detriment of the poor unfortunates for whose relief the institution was created; and

"*Whereas*, There are in each of these hospitals seven or more trustees, men carefully selected because of their fitness to manage hospitals for the insane, but who, under the laws which govern the hospitals named, have scarcely the least part in the management of them, so entirely subservient are they to the Superintendent, although by the public held responsible for whatever wrong or neglect of duty may appear in the management of the institution, and what adds to their mortification is the fact that, however desirous for much-needed reforms, they have no power to effect them without permission of the Superintendent; and

"*Whereas*, The law which governs the Eastern Hospital at Norristown—also a State institution—does not create a Superintendent, but empowers its thirteen (13) trustees to have the sole control and management of the entire institution, its physicians and employés; and

"*Whereas*, The wisdom of our law-givers in thus giving the care of the institution to the trustees, and not to the Superintendent, has been grandly manifested by the success attained in the treatment of the thousands of insane who during the few years of its existence have been cared for within its walls, and by the condition of the more than sixteen hundred (1600) there at this moment—almost if not quite as many as are cared for in the hospitals of Harrisburg, Danville and Warren all combined—where, though every ward has been filled to its greatest capacity, the per cent. of recoveries has been greater than in any other of our State hospitals; and

"*Whereas*, It is the sense of this Society, this convention of physicians deeply interested in the welfare of the insane, and anxious that our State shall be second to none in furnishing to these unfortunates the

greatest attainable comfort and most efficient treatment, and believing that the change in management in the hospitals at Danville, Warren and Harrisburg, where almost everything is under the control of the Superintendent, to that of the Eastern hospital, in which the supreme authority and responsibility are with the Board of Trustees, would be an advance in the right direction,

"Therefore: *Resolved*, That a committee of —— persons be appointed by the President of this Society, to memorialize the Legislature for such change in the laws governing the three State hospitals above named as will confer on their Boards of Trustees full and exclusive power of management, and make it obligatory on them to provide that the medical chiefs and their assistants shall perform only such duties as pertain to their office as physicians or practitioners of medicine."

The Board of Public Charities published and sent to the Trustees of all the State Hospitals the following:

"FEMALE PHYSICIANS IN STATE HOSPITALS FOR THE INSANE.

"*Whereas*, There are in the medical profession thoroughly educated and experienced female physicians, who would be entirely competent to perform all the duties of Resident Physician in a State Hospital for the Insane, and

"*Whereas*, The Trustees of the State Hospitals for the Insane at Harrisburg and Norristown, and the Managers of the Philadelphia Hospital for the Insane, at Blockley, have for many years given the charge of the female insane in these institutions to Female Physicians, with the most satisfactory and gratifying results,

"*Resolved*, That the Committee urge upon the Managers and Trustees of the Hospitals for the Insane, at Dixmont, Danville and Warren, that they organize their management, as soon as circumstances will permit, to conform with the Act of June 4, 1879, which permits the Trustees of the State Hospitals to appoint "a skillful female physician, who shall reside in such asylum or hospital, and who shall have the medical control of said female inmates, who shall report to the Superintendent and also to the Trustees."

It is matter of regret that I cannot give in full the excellent remarks of Dr. Morton on these subjects, as read at Harrisburg.

In the hope that physicians will examine this subject and speak for the right, I am now content to leave it with them.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, November 1, 1888.

(*Concluded from p.* 657.)

Dr. T. M. Drysdale in the chair.

Dr. Hirst reported six cases of

Puerperal Insanity.

In the last eighteen months he had seen six cases of puerperal insanity, an unusual experience for an obstetrician, since, according to Fordyce Barker, this condition only occurs once in four hundred cases of labor. Of these six, four were illegitimately pregnant; two had mania, while four presented a melancholic, apathetic appearance, and seemed indifferent to all about them. Three of the women recovered their reason; two are apparently hopelessly insane; and one died from a septicæmia which was associated with and perhaps caused the mental state. One case was sudden in its onset, violent in its manifestations, but short in its duration; the woman was told two weeks after confinement that her perineum was ruptured and would probably have to be sewed together. She almost immediately became maniacal and remained so for about three weeks. A correct idea of the most common variety of this affection, of the prognosis and the best means of treatment cannot be obtained from an obstetrician's practice, which must necessarily be small; but must be sought for in records of such cases presented by competent observers, who, especially if in charge of asylums, have to deal with a large number of them. Studies of more than 800 of these cases by Clark, MacLeod and Wiglesworth have recently been published. From them it appears that the maniacal form of the disease is the most common; that a large majority of the cases recover, usually within six months; that when death occurs it is commonly traceable to sepsis, which is so often associated with puerperal insanity, although a few cases die from maniacal exhaustion; that the best treatment is the Weir Mitchell rest cure. Heredity plays a most important part in the etiology of the disease; very often the subject is mentally and physically depressed. It seems not very uncommon for the chorea of pregnancy to develop into insanity; this happened in one of my cases.

Dr. Joseph Price exhibited specimens.

The first specimens shown were from a case operated upon that very day. He had placed them in a bath, in order that the adhesions might be plainly seen. The pavilion in both tubes was closed; there was no semblance of a fimbriated extremity; the tubes had been separated from the ovaries. He could not enucleate the ovaries in this case until the fundus of the uterus had been shelled out. He always floated the appendages in water, in order that it might be seen that there were adhesions, before the spectators left the room. A simple examination was liable to provoke harsh and often unprofessional criticism. There was a gonorrhœal history in this case, and the woman suffered greatly. The last child was born ten years ago, and since then she had suffered constantly. Locomotion was painful and difficult; stepping from a curb-stone or turning over in bed caused great pain.

The second specimen consisted of both Fallopian tubes and ovaries, illustrating the condition known as hæmato-salpinx. In shelling them out, the pavilions were opened and found to contain a coffee-colored material; the condition might be termed hæmato-salpinx, although it is not exactly what is generally recognized as hæmato-salpinx. With the fluid or concretion from a typical hæmato-salpinx a black mark can be made on a white wall.

He scarcely knew how to describe the next specimen. The peritoneum was studded with hard bodies; it was difficult to get into the pelvis. A peritoneal cyst, containing a quart or more of fluid, was opened. The tubes were adherent, large and cheesy; the ovaries were clearly cystic. The adhesions were very general, and it was difficult to start the enucleation. The pavilions were closed. In these cases, he said, the adhesions are often so strong that the ovarian tissue is torn, and he has often left a small piece of ovary on the sacrum in trying to make the separation.

Dr. William Goodell understood that the peritoneum was covered with papillary deposit in the last case. Then it must be a papillomatous cyst of the ovary, and the papillomata have either grown through the wall of the ovary to its surface or else they have developed on the surface. In these cases he had found universal infection, with papillary deposits everywhere on the peritoneum. Sometimes these growths have proved malignant, at other times benign.

Dr. W. H. Parish asked if the deposits might not be tubercular. It would require the microscope to determine their character. They looked very much like what he found in a case of tubercular deposit in the peritoneum, associated with adhesions and thickening of the tubes and ovaries. He had opened the abdomen and removed the peritoneal fluid; this had been followed by wonderful improvement. The abdominal tension and distension disappeared, and have not returned. The patient is now a well woman. Previous to the operation, she was almost bed-ridden. He would say, in regard to the specimens before him, that they do not exhibit their condition as they do at the time of the operation; and he had thought that criticism on the propriety of the operation was not altogether fair when made by men who have not seen the specimens in the fresh state. There is a great difference in the appearance of specimens when presented here, and at the time of the operation. Moreover, the inflammatory mass and the adhesions about the appendages are not fully indicated by the specimens after removal.

Dr. T. M. Drysdale saw the specimen in its fresh state. It did not then present the flattened appearance of a tubercular deposit, but had the rough warty look of a papillomatous growth.

Dr. Baer said that the specimens which had just been presented would seem to sustain him in the view which he had expressed regarding the pathology in these cases, viz., that the condition of the tubes usually met with is one of a general non-purulent inflammatory condition, rather than of pyosalpinx; for there is not one of the latter character among the specimens presented. This is the condition he usually meets with in his operations. In one of these cases the disease is said to result from gonorrhœal infection; yet it is not stated that pus was present. There is no question, however, as to the gravity of the disease and the necessity of the removal of the appendages in all but one of the cases presented, whether pus was present or not. The tubes were so hypertrophied and dilated, and the ovaries so thoroughly diseased, that it could never be hoped to cure these patients by any other means than by removal of the appendages. But the specimen which has been placed in water for the purpose of demonstrating that inflammatory adhesions really did exist, and in which the ovary and tube do not seem to be seriously diseased, deserves attention. He had himself been criticized for removing such tubes and ovaries, and perhaps justly;

for it does seem, and he believes it is true, that a patient presenting such slight disease that it is necessary to place the specimen in water to demonstrate the adhesions to a society of experts, might be cured without operation. In such a case there must on physical examination have been very little thickening of the tubes and ovaries felt through the abdominal wall or vagina; there must have been such slight evidence as to require an expert like Dr. Price and some others to determine the presence of disease. He had no doubt that many cases of pelvic peritonitis, even recurring peritonitis, are cured by spontaneous absorption of the inflammatory exudate, without treatment; but he was sure that with treatment, by rest, etc., he had cured many cases in which the tubes and ovaries have been as adherent as in this case, and even worse. In this case there must have been found very little thickening of the organs and tissues involved, as felt through the vagina and abdominal wall. He had seen such patients get well and bear children. It is always well, however, to tell the patients that the disease is liable to return, so that they may observe greater care. But it cannot be doubted that many cases of pelvic peritonitis recover entirely, and do not necessarily have a recurrence of the disease.

Dr. M. Price said that he would take great pleasure in showing Dr. Baer the next pus-tubes he removed. The specimens before him were as pretty examples as he had seen. In one case there were three abscesses in one tube, showing positively that in such cases the treatment of Martin by drainage through the vagina could not possibly do good. There might be cases in which such treatment would answer the purpose; but, where the tube is sacculated, each sac containing pus, and in addition, as a result of leakage, there are abscesses in the cellular tissue of the pelvis, it is not applicable. He did not believe these abscesses ever occurred except as the result of leakage.

Dr J. M. Baldy thought that it did not require an expert to diagnosticate such tubes as were presented and had been placed in water. The inflamed tubes are plainly and easily recognized. They are felt to the right or left of the cervix or posteriorly in the *cul-de-sac* as an irregular hard mass, which masses it was the custom in times past to diagnosticate cellulitis. When removed the specimens often looked very small. With reference to the absorption of adhesions, he did not believe that this ever occurred. He believed that a tube and ovary, once adherent, were always adherent, and that no form of treatment would produce absorption. He had seen any number of cases treated medically for years by the most skilfull men, but they had come finally to the knife. At the operation there had been found simply adherent tubes and ovaries. As far as the possibility of these cases becoming impregnated was concerned, where the disease was bilateral, such cases were simply examples of mistaken diagnosis. When the fimbriated extremities or uterine ends of the tubes are closed, it becomes a physical impossibility for impregnation to take place.

Dr. Baer said that he would be glad to examine any specimen which Dr. Price might wish to bring; but if he expected to show him in a pus-tube something that he had never seen, it would not be necessary for him to come. He then related the following case in support of his position. Six years ago a woman was sent to him, and on examination she was found to have a small circumscribed tumor attached to the posterior surface of the left broad ligament. It seemed to be and afterward proved to be an inflamed ovary which was surrounded by a mass of lymph, that fixed it in the prolapsed position which it occupied. It could not be ascertained certainly, but the tube was thought also to be fixed by the lymph mass. The patient had had a child nine years before, and subsequently means for the prevention of conception had been resorted to for a number of years. She now desired children, but sterility had followed this long prevention of conception. She was placed upon treatment consisting of rest, massage, electricity, the use of iodine, hot water, etc. She began to improve after the second or third week of treatment. The tumor, which was not larger than a walnut, gradually became smaller from absorption of the lymph around it; both the uterus and the ovary became more mobile, and within two months the ovary had returned to almost its normal size. The opposite side was also affected, but less severely. This woman has borne two children since. Would it have been just to the patient to have removed the tubes and ovaries in this case? Is it right to sacrifice the ovaries and tubes in cases of this character without first making an effort to cure without operation? In some cases, the main pathology is a pelvic peritonitis with adhesions, rather than ovarian and tubal disease. He holds that criticism is just under these circumstances.

Dr. H. A. Kelly thought that the discussion aroused by these specimens had

assumed a very important direction, and he must heartily agree with Dr. Baer; for he had often seen light adhesions of uterus and ovaries absorbed while under treatment. There is still too much *furor operandi*, and too little diagnostic precision. Men must cultivate their tactile sense more. The mere operation is often nothing. He actually had one patient under his care who was told by a doctor in August that there was a pus-sac in her pelvis, and if she did not at once consent to operation her life was in imminent danger. Being his patient, she refused to be railroaded into an operation in this way, and came to him on his return. He then found her pregnant. How careful men should be; how little is in the operation, how much in the judgment which decides it! Brandt's treatment of massage deserves careful trial in cases in which there is no fluid accumulation in the pelvis. He had long since ceased to bring specimens of freshly removed tubes and ovaries before this Society for exhibition, as it is the same old story every time, and—he was ashamed to repeat it—big tubes, adherent ovaries, pus and water or blood, intestinal and mesenteric adhesions tied off, pelvis flushed, drainage-tube. He had six cases in the past week, and except one, most difficult enucleations; but he had no new suggestion to offer. It is due to the dignity of the Society that as years go by, we should at least make some advance in our knowledge; but here we are to-day using the same terms we used three years ago—hydrosalpinx, pyosalpinx, hæmato-salpinx — describing merely the fluid contents of the tube, without any reference to the actual disease, the causative factor. What is the process which produces these final stages? And are the water, blood or pus contents of the tube the whole disease, or are other structures as well the seat of the disease? These questions are most important, both as regards prophylaxis and as regards the mere technique of the operation. We want more natural history of these diseases, and more pathology, then perhaps we would devise better ways of relieving these patients.

Dr. W. S. Stewart understood, in the case referred to by Dr. Baer, that only one ovary was involved. Might it not be possible that where the tube of one side was bound down by adhesions, the tube of the other side might have performed the proper function for both? Or that perhaps all of the functions had been performed by the ovary and tube of the opposite side?

Dr. Joseph Price was delighted to hear that it is time to cease removing healthy ovaries. He had never removed ovaries that were not diseased, for vague nervous symptoms. He should be glad to have any of these specimens examined by pathologists, and if they should say that anything could possibly pass through such pavilions he would be greatly surprised. These cases had been treated medically by the best men in the profession. The vaginal vault could be rubbed and painted, tickled with electricity for years, but this would never release the pavilion. Drs. Drysdale and Parvin were both present at the operation, and if they had any criticism to offer, he thought they would have made it. He would be glad to know of any other successful way of treating these old chronic cases, other than by removal, but he did not.

Dr. Baer, he thought, did not mean what he said about treating these patients. We may have an adherent ovary with the pavilion free. The only way in which such a case could be diagnosticated was by the history. These cases can, he said, be easily classified; they are all distinct diseases. It is folly to say that a tube containing pus is not a pus-tube; again, one containing blood—give it a better name if you can than hæmato-salpinx; so with hydrosalpinx—give it a better name if you can. If anyone can go further than Mr. Tait has done, let him do so. Men do remove ovaries for ovaralgia and so-called cirrhotic ovaries. He thought that all such operations should be condemned. It is as absurd to remove a so-called cirrhotic ovary as it is to trephine the head for clavus hystericus, in the same hysterical patient. He insisted that he operated for actual disease, and that no one had a right to touch a patient except for disease. The results of the Battey operation are not good, and it is condemned throughout the country.

Dr. Montgomery reported a case of

Vaginal Hysterectomy

with the following history: Mrs. M., a patient of Dr. T. O. Noch, 40 years old, the mother of five children and the victim of a large number of miscarriages, has been suffering for the last six years with frequent hemorrhages, which for the past few months became almost continuous. He saw her in consultation with her physician some months since, and upon examination found an excoriation on the posterior lip extending into the canal of the uterus. It was advised that the surface be touched with chromic acid, and subsequently treated with soothing

applications; if there was not rapid improvement following this course, a section should be removed for microscopical examination. Failure to arrest the disease, and the demonstration of the presence of epithelioma by the examination of a competent microscopist, led to the decision to extirpate the organ. Oct. 4, at the request of Dr. Noch and assisted by him and Drs. West, Rively and Mr. Croskey, Dr. Montgomery had performed the operation. The patient was placed in the lithotomy position, the vagina separated by retractors, and the cervix transfixed by a ligature. The vaginal mucous membrane was cut through, encircling the cervix, the submucous tissue separated to the peritoneum in front and back; the broad ligament was cut laterally sufficiently to make sure to free the ureters from injury in securing the ligaments. An opening was now made into the peritoneal pouch posteriorly and a large sponge inserted; two fingers were inserted, the fundus pushed forward and the anterior opening was completed. A pair of strong forceps so constructed as to make equal pressure in their whole length was applied upon each side of the uterus and the organ removed. Some vessels not included in the compression forceps continued to bleed, so that a number of small forceps were applied. In all, some eight forceps were applied and left hanging from the vagina. The sponge was withdrawn from the pelvis and the vagina lightly packed with iodoform gauze. The small forceps were removed at the end of thirty hours and the large ones in sixty hours. The convalescence of the patient was uninterrupted and without event. The highest temperature reached was 100°, on the third day.

Dr. Montgomery also presented a case of

Supra-Vaginal Hysterectomy.

The patient, 29 years old, married, never pregnant, has been suffering for several years from severe menorrhagia. One year ago he saw her with Dr. Strittmatter. Upon examination he found a large fibroid uterus. She presented evidence in her blanched face of having suffered from severe hemorrhage. The removal of the uterus by the supra-vaginal method was advised. She was advised by her friends to consult other parties, who informed her that such an operation would be certainly fatal, and advised the removal of the ovaries. The hemorrhage still continuing, she went to Dr. Strittmatter's private hospital, and at his request Dr. Montgomery performed the operation, in which he was assisted by Drs. Strittmatter, Moylan and Messrs. Starkey and Sangree, medical students. An incision about six inches long was made and the tumor was with difficulty lifted up. The ovaries were enlarged, cystic, adherent and behind the uterus. The removal of the uterus was more readily accomplished than would have been the removal of the ovaries. For the purpose of returning the pedicle, the neck of the uterus was surrounded with a rubber ligature and the tumor removed, leaving two large flaps; these were sewed together by a number of continuous sutures of catgut until the flaps were completely coapted; upon the removal of the ligature, however, there was so much bleeding that it was thought better to use the Tait clamp. The peritoneum was sewed fast to the stump of the uterus below the clamp. One ovary had been removed and the other, owing to extensive adhesions, was permitted to remain. The wound was closed with silk-worm gut, dusted with iodoform and covered with iodoform gauze and absorbent cotton. She stood the operation fairly well and suffered but little from shock; the following day the temperature was over 104°. Believing it to be due to the dressing, Dr. Strittmatter applied a carbolized gauze dressing and the next day the temperature was 99°. The subsequent convalescence was all that could be wished for, and the wound has now healed with the exception of the lower angle where the stump was fastened.

Dr. Montgomery read the history of a case of

Tubal Pregnancy

for Dr. Noch.

Mrs. ——, 28 years old, married, has had four children, labors normal. Had menstruated regularly until August 17 last, with no evidence of it since that time. The patient thought herself pregnant and felt nothing unusual. She arose one morning from her bed and fell to the floor. She went back to bed and, not improving any, Dr. Noch was sent for. He found her with a very pallid, pinched, and wax-like condition of the face; body and extremities cold and perspiring. Respiration was very rapid and shallow, and the breath cold. Heart's action was regular but very weak; pulse small and compressible and very rapid; temperature under 94°. There was marked stupor, but she could be aroused, with difficulty, to answer questions. The uterus was somewhat enlarged, cervix slightly softened, and there was a gradual

oozing of a coffee-colored fluid from the os. She had very little pain but felt extremely weak. Her whole appearance indicated internal hemorrhage. The diagnosis of tubal pregnancy with rupture was made. Laparotomy was considered, but deemed useless for fear the etherization would cause heart-failure and death on the table. Diffusible stimulants were freely given and the local application of heat was used in the hope that reaction might occur and laparotomy be possible. She continued to fail and died at 10.30 P.M., never having recovered from her shock. The post-mortem showed an abdomen filled with blood-clots. A small fœtus was found in the left inguinal region, floating in its sac, which was still unruptured. The tube was found to be ruptured midway between the uterus and ovary, leaving the placenta still in the tube. Development had advanced to about the 7th or 8th week.

Dr. Montgomery then exhibited a clamp he had devised for clamping the broad ligaments in cases of vaginal hysterectomy. The two blades were each grooved and could be closed with a parallel motion. They were joined at the top by a permanent joint. The surfaces of the blades were long enough to include the whole ligament in one grasp.

Dr. Wm. Goodell was sorry he had overlooked the fact that Dr. Montgomery had a case of this kind to present. He should like to have brought a pair of Doleris's forceps which he received through the kindness of Dr. Lusk. It is a clamp analogous to the one shown, but it has the obstetric lock. The blades can be disarticulated and one of them ends in a short hook by which the broad ligament is caught at its upper edge and brought down. He had not had occasion to perform the operation since he had received the clamp, but he had had two cases, one of which was fatal. The operation with the ligature was a tedious one and the use of the clamp must shorten it. He believed that we were indebted to Richelot for the clamp.

Dr. J. M. Baldy asked how Dr. Montgomery would apply his clamp. It was much like the one figured in Greig Smith's book, except that it was permanently locked above at the joint; while Smith's could be taken apart, one blade introduced on each side of the ligament and then the joint made above. He could not see how this one could be easily applied unless the abdominal cavity were opened and it were slipped down from above.

Dr. Parish had seen the description of a clamp with separable blades, the deviser of which he could not recall. One of the blades has a long fenestrum open at the distal end, and the other blade fits into this open space. This gives uniform compression of the broad ligament. With the instrument shown the compression may not be uniform.

Dr. Montgomery said that in the majority of cases there was not much infiltration of the ligament. After cutting the ligaments in the manner described, the uterus can generally be readily everted, the fundus of the organ brought to the vulvar orifice, and the clamp applied from the outside. Even in those cases in which the ligament is not readily drawn out, he saw no reason why the instrument should not be pushed into the abdominal cavity and one blade brought down on each side of the ligament. If the instrument were clean it would do no harm to the peritoneal cavity.

Dr. Baldy said that the specimen of tubal pregnancy was interesting, as demonstrating Tait's theory of the pathology of extra-uterine pregnancy. Tait holds that rupture takes place into the broad ligament, and that the fœtus then goes on to develop, or a secondary rupture subsequently takes place into the abdominal cavity. This process is most beautifully shown in this specimen. The cavity of the tube and broad ligament form one and the rupture has taken place into the peritoneal cavity.

Dr. H. A. Kelly described some

Glass Catheters.

Some five years ago he was hard pressed to catheterize a woman suffering from a distended bladder; not having his catheter with him, and being at some distance from his office, he took the crooked glass tube out of the baby's feeding-bottle, and drew the water with perfect ease. Since that time he had more or less constantly used glass catheters, which he had had constructed for the purpose. He placed far more confidence in the glass than in the metal catheters. The manifest requirements of a good catheter are that it should be easy to introduce, draw the water quickly, and be readily cleansed afterward. The first two requirements are readily answered by any material of which catheters are commonly made. In the last lies the difficulty. It is impossible to be sure that the inside of the catheter is clean. He has hitherto directed his nurses in his hospital, where the catheter is in constant use, to keep

them, when out of use, in boiling water. He is now using glass catheters constructed like those he exhibited. They are very cheap, safe (never breaking when in use), and cleansed with ease and certainty. In a hospital a number can be kept standing in a jar containing a disinfecting solution. The device of catheterizing with a glass tube is so simple that he was sure many present, as well as elsewhere, must have resorted to it long before this. He was also not surprised this summer, when he found well-made glass catheters for sale at the instrument-makers' in Berlin. He presented two patterns, which were sold at twenty-five cents each.

ITALIAN SOCIETY OF INTERNAL MEDICINE.

FIRST CONGRESS, AT ROME, OCT. 20 TO OCT. 24, 1888.

The organization of this Society has taken place quite recently, and has been brought about by the coöperation of all the professors of Clinical Medicine of the Italian Universities. The Congress has been quite a success. About five hundred physicians attended its meetings.

Saturday, October 20.

President's Address.

The PRESIDENT, DR. BACCELLI, of Rome, after having welcomed the members of the Congress, spoke of the great progress which has been made in these last years in experimental medicine; he said that such a meeting as the present was exceedingly useful, as it united professional men who cultivate synthesis in the great and extensive field of clinical studies. In practice one must take everything that is useful; but there are three branches at present before us, which claim all our efforts and attention, namely, bacteriology, therapeutics, and neuro-pathology.

In regard to bacteriology, we shall soon know, it is hoped, what we may regard as pathogenous or specific. Extensive researches, however, are still necessary to bring about this result. In regard to therapeutics, we are in a very excitable period; the number of new drugs is enormous, and is increasing every day. I think this is due to the creation in Italy of "Therapeutical Clinics," which too often lower the human being to the rank of an animal on which experiments are performed.

Neuro-pathology, by the localization of the cerebral centers, opens a new way to the explanation of the numerous diseases which have their origin in the central nervous system.

PROF. TOMASELLI, of Catania, read a paper on

Quinine Poisoning, or Ictero-hematuric Fever,

in which he said he had observed, during the past year and in many instances, that in certain malarial patients, under certain conditions, quinine did not have any marked action on the malarial condition; but, on the contrary, brought on a special kind of intoxication, the prominent symptoms of which are fever and hematuria. He has observed that this intoxication is more liable to present itself when there is a chronic or acute malarial condition, and a depressed state of the patient. The symptoms produced occur from one to six hours after the ingestion of quinine, while the patient is free from fever; he is suddenly taken with a marked chill, which in one or two hours brings the fever up to 106°.7 to 108°.5 Fahr.; then vomiting sets in, with diarrhœa and a great desire to urinate, the latter accompanied by the passing of bloody urine. Sometimes a jaundiced condition presents itself at the same time. This paroxysm usually lasts twenty-four hours, and terminates by a fall of temperature. The symptoms just mentioned gradually disappear, but the patient is left in a very weak condition, and remains jaundiced, if this complication has occurred. If quinine is not stopped and these paroxysms are allowed to recur, the patient falls into collapse and dies. The post-mortem examinations have proved that the blood is the chief seat of the disease; the red globules are discolored and reduced in number when compared with the number of white corpuscles. The urine is red, bloody, contains biliary coloring matter, epithelial cells, altered red corpuscles, and fibrinous casts. Hemoglobinuria is also more frequent than hematuria. This ictero-hematuric fever is often mistaken for a fever met with in Algeria, which, however, is a malarial ictero-hematuric fever; it is also confounded with hemoglobinuria due to cold. This disease must also be distinguished from the form described by Bretonneau, which occurs in patients who have received very large doses of quinine that have produced great gastro-intestinal disturbance. It is also to be separated from the quinine fever of Zimmermann, described

by this last author, and found in those persons who pulverize cinchona bark.

The disease described by Tomaselli is due exclusively to the preparations of quinine, which have a dissolvent action on the blood and decompose it very rapidly; there is a destruction of the red blood corpuscles, and an elimination of hemoglobine. Dr. Tomaselli, although not opposing altogether the use of quinine in the treatment of malarial diseases, thinks that in certain cases even very small doses of the remedy may produce dangerous symptoms; in such cases one must not hesitate to use other remedies against the malarial poison.

Dr. Bozzolo, of Turin, asked if Dr. Tomaselli had observed in the red globules the plasmodium studied by Marchiafava and others.

Dr. Carderilli, of Naples, does not think that quinine intoxication is found only in malarial patients; he records a case in which a very small quantity of quinine would produce hematuria in a case of pseudo-leukæmia, which presented no traces of malaria. He does not admit that ictero-hematuric fever is a result of the treatment with quinine, for he mentions an epidemic that occurred lately in which this disease was observed, although some of the patients received no quinine at all. He thinks that the fever is of a special order, the origin of which has not yet been discovered.

Dr. Giuffré, of Palermo, has observed two malarial patients, who presented hemoglobinuria immediately after the administration of quinine.

Dr. Marchiafava, of Rome, has often observed the ictero-hematuric fever in the hospitals of Rome, where there are a great many malarial patients. There is no doubt as to its malarial origin. These fevers, contrary to Dr. Tomaselli's statements, have been cured with quinia. The important fact is that the symptoms disappear under the influence of the preparations of quinine, whereas the contrary would be the case if they were due to quinine intoxication.

Dr. Maragliano, of Genoa, said that as we find in malarial patients an alteration of the thermic centers, with involvement of the nutritive function of the blood, it is not impossible that in certain patients the action of the quinine as observed might be quite contrary to what it usually is; that is to say, by its action on the thermic centers which are acting badly, it might produce a rise of temperature; and by its action on the blood, which is very much altered, hemoglobinuria might be produced.

Dr. Baccelli, of Rome, said he did not accept the name quinine intoxication; for, should it be a real intoxication, we should observe it in every case, with the same rapidity and the same severity. He also calls attention to the fact that certain malarial fevers have for their principal symptoms hematuria and jaundice, which, instead of becoming worse, disappear under the influence of quinine. Still he admits that some patients, suffering from malarial disease and presenting hematuria and jaundice, might find their condition aggravated by the administration of quinine; but these are rare cases.

Dr. de Renzi, of Naples, read a paper on the

Treatment of Pulmonary Tuberculosis,

and said that in Naples, one-quarter of the mortality must be attributed to phthisis. He has tried every known method against the disease. From his experience, he found that preparations of iodine, as well as sulphurous inhalations, have given him the most satisfactory results. He has used with great success inhalations of sulphurous acid gas as well as of sulphuretted hydrogen, and has found that these agents have greatly decreased the oppression as well as the continuous and troublesome phthisical cough. Iodoform has been found by him very useful in diminishing cough, expectoration, dyspnœa, and in reducing the temperature; he has been very successful in diminishing the diarrhœa of phthisical patients by giving inhalations of iodine dissolved along with iodoform. All that can be done up to the present, he thought, is only palliative; he has administered alkaline carbonates as he has noticed that the blood of phthisical patients has lost some of its alkalinity; but he has not obtained any marked benefit to his patient by their use. In an experimental way, he has also found that when he inoculated guinea-pigs with the tuberculous virus, and then submitted some of them to inhalations of iodine, those which inhaled the iodine lived much longer than those which did not undergo the treatment, although finally they all died.

Dr. Pettoruti, of Naples, thinks that enemas of sulphuretted hydrogen can be very useful, when administered in the early stages of the disease; and he records two cases in which the physical signs entirely disappeared under this treatment, and he considers his patients cured.

Dr. Riva, of Parma, has studied espe-

cially the three surgical methods of treatment of pulmonary tuberculosis: pneumectomy, pneumotomy, and the interstitial or direct injections of substances into the lung tissue. The first method, or pneumectomy, he does not think advisable; for the extirpation of a part of a lung has not, up to the present time, prevented a recurrence of the disease, for when the operation was undertaken the neighboring peribronchial glands have all been more or less involved, and the total extirpation of the lung, under such conditions, would only be a remarkable surgical operation, but without any benefit whatever to the patient; on the contrary, this method could only be resorted to with propriety in the early stages, when the disease is entirely localized. But it would be a very difficult matter to find a patient who would consent to run the risk of his life at such an early stage of the disease by submitting to this formidable operation.

The second method, or pneumotomy, should also be resorted to as soon as a pulmonary cavity is discoverable; but is it not then already too late to interfere? Of all the cases he has collected he only found that in one-fifth of the total number of cases was there a temporary amelioration or great diminution of the frequency of the cough, reduction of the temperature, or an increase in the general weight of the patient.

The third method, parenchymatous intrapulmonary injections, he has resorted to in many cases, with good results in some, but never a complete cure. The object in view with such injections is to produce a cicatrization of the pulmonary cavities, or to destroy the tubercle bacillus. For the cicatrization of the pulmonary cavities he thinks the injections useless, for in using them some of these cavities are sure to be omitted; hence the treatment remains imperfect. For the destruction of the bacillus, he thinks these injections might be useful if a sufficient quantity of the antiseptic liquid is injected, so that the parts injected are perfectly saturated with it. He has injected from two and a half drachms to six and a half ounces at a time. To this process he gives the name "pulmonary inundation," which it really is. To enable patients to resist the injection, however, only fifteen minims must be injected a minute. He has never obtained one single cure, but he has observed marked relief, due to suppression of the cough and pain, marked improvement from the pre-existing dyspnœa, reduction of temperature, and increase of weight, of appetite, etc. The solutions used were of corrosive sublimate and camphorated chloral.

Dr. Ampugnani, of Catania, and Dr. Sciolla, of Genoa, presented the result of their experiments with inhalations of hydrofluoric acid. They have had very good results; the skin and mucous membrane did not seem to be affected by this agent.

Sunday, October 21.

Prof. Bozzolo, of Turin, read a paper on

The Etiology of Pneumonia,

in which he said that in accordance with the results obtained at the laboratory of the University of Turin, he had arrived at the conclusion that pneumonia, which is regarded as a contagious, epidemic, infectious disease, is due to the presence of two schyzomycetes—Friedländer's streptococcus and Fränkel's diplococcus. Out of a series of twelve experiments on the living expectoration, he has been able to isolate the diplococcus of Fränkel in eight cases, but never has isolated Friedländer's streptococcus. In addition to these he has also seen the staphylococcus pyogenes aureus and citreus; from his experiments he attributes the principal *rôle* in the etiology of pneumonia to Fränkel's diplococcus. Dr. Bozzolo also thought that pneumonias, which have not for origin Fränkel's microörganism, differ both in their pathological anatomy and in their symptomatology from the ordinary fibrinous pneumonia.

Drs. Sciolla and Trovati, of Genoa, have obtained blood from a pneumonic patient and have introduced the same directly into the heart of an animal, and have found that it had a toxic effect, probably on the cardiac muscle and its contained ganglia. Moreover, they have observed that this poison can still be found in the blood of pneumonic patients when the fever has disappeared. They recommend, as a rational treatment of pneumonia, several blood-lettings, which take away each time directly a certain amount of the poison.

Dr. Lucatello, of Genoa, has found that the serum of the blood of pneumonic patients is sterile, and he explains this fact by the secretion of toxic substances by the pathogenous microbes.

Dr. Maragliano, of Genoa, read a paper on the

Treatment of Pneumonia,

in which he drew attention to the fact that,

the infectious nature of pneumonia being admitted, efforts must be directed to the elimination, if possible, of the toxic substance which has a tendency to paralyze the cardiac muscle.

Although the disease has a regular course to run, he does not recommend expectation, but thinks the patient must be sustained all the time to enable him to pass successfully through the dangerous period. He is opposed to direct injection of solutions of corrosive sublimate into the lung, which he has done himself, but without any marked benefit. He recommends blood-letting repeated two or three times during the course of the disease; from three to six ounces of blood are taken away with remarkable benefit to the patient; out of twelve patients he has treated in his medical clinic, he has had not a single death. He thinks, with the preceding speaker, that the occasional abstraction of a certain amount of blood takes away at the same time a certain amount of toxic matter, and so checks cardiac paralysis, and at the same time reduces the blood-pressure. He is opposed to giving ipecacuanha in the early stage of the disease, for he thinks it diminishes the force of the heart; he prefers digitalis and strophanthus, with small but repeated doses of alcohol; he also gives very light food. Against fever and the nervous symptoms he uses cold baths at 86° F., reduced gradually, by the addition of cold water, to 68° F.

Dr. Cantani, of Naples, states that the dangers of pneumonias of different origins are cardiac paralysis and the infectious cause. He does not think, with Prof. Maragliano, that the small quantity of blood which is abstracted from the pneumonic patient by blood-letting is sufficient to prevent the action of the toxic agent which the blood contains; he would admit blood-letting if the pulmonary veins could be bled directly, but, not being able to do that, he rejects blood-letting except when there is a high blood-pressure.

Dr. Sonsino, of Pisa, said that if blood-letting could make the toxic products disappear from the blood in pneumonia, why should it not be used in every infectious disease? But such treatment only weakens the patient, without benefit to him.

Dr. Bianchi, of Florence, has observed that in pneumonia the right auricle is especially enlarged; in children even he has found the heart increase; he has verified this fact by intracardiac injections of water in post-mortem examinations, producing a large dilatation of both right ventricle and auricle. He advises blood-letting in these cases, especially in children.

Dr. Hippa Felice, of Sardinia, said he did not believe in the modern bacterial theories. He obtains good results in his practice by one or several blood-lettings, or the local abstraction of blood by means of leeches.

Dr. Serafini, of Pisa, has made the following experiments: He has injected from fifty to sixty minims of a culture of Friedländer's pneumococcus into two sets of dogs; some of them were bled, while the others were left alone; all the first died, while those which were not bled lived.

Dr. Baccelli, of Rome, said that blood-letting must be reserved for very serious cases; he recommends the inhalation of oxygen in the period of asphyxia of this disease, having obtained very good results from its use.

Dr. Roncisvalle, of Catania, has found, in several cases of pleurisy, the presence of the diplococcus and streptococcus of pneumonia; he concludes from his observations that certain pleurisies are of an infectious character.

Prof. Maragliano recommends and uses ipecac only at the period of the paralysis of the bronchi. In regard to bleeding, he says that no one has yet demonstrated that blood-letting is harmful. The pneumonic patients do not use up their red blood-corpuscles more than phthisical patients; hence a certain quantity of them may be abstracted if it is found necessary and useful.

(*To be continued.*)

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, November 15, 1888.

The President, A. Jacobi, M.D., in the chair.

The President explained that it was the custom of the Academy once a year to invite the public at large to a meeting at which some representative man in the profession would deliver an address of general interest, and to call the attention of the people to the work done by the Academy and the purposes it was to fulfill. Many of the invited guests availed themselves of the opportunity presented to inspect the halls, and large library which is always open to the public as well as to the profession.

Dr. D. B. St. John Roosa was then introduced. He had selected as the subject for his discourse:

How to Effect Unity in the Profession.

He showed that no dissensions divided the profession in the State of New York during the first part of the century; that it was not divided into schools, but that all who were permitted to practise in the State went under no other title than that of Doctor. The State Society and the County Societies were a part of the legal machinery of the State; and there were not, as now, a Homœopathic State Medical Society, an Eclectic State Medical Society, as well as that to which the doctors present belong. These divisions had arisen from contentions which had served no good purpose, but had done incalculable harm. Had the members of the county societies not undertaken to expel those who were legally qualified to practise, and had been educated with themselves in good medical schools, simply because they did not agree with them regarding theory and practice, the profession in New York would have remained a unit. The trouble arose not from attempts at restricting ignorant Thomsonians, or eclectics as they were now called, but those who were well educated, yet who were not supposed to be orthodox on therapeutics and theory regarding the action of medicines. Our forefathers might have been able to judge what constituted orthodoxy in this respect, and whom to declare heretics; but to-day it would be difficult to draw the dividing line. Some of the accepted remedies and theories of practice of our forefathers now appear to the profession little less absurd than those of sects whom they cast out.

It was a mistake, he said, to permit medical colleges, notwithstanding their present advanced rank, to send out graduates who are required to pass a further examination before being allowed to practise in the army and navy or public hospitals, and yet who can at once enter upon the duties of a physician in relation to the general public. There should be a State board of medical examiners, such as has been suggested by the Medical Society of the State of New York at its last two meetings, urged by Dr. Loomis, the late President, and by the counsel of the Medical Society of the County of New York, Mr. Purrington. The legally established colleges should retain the privilege of conferring the title M.D. on their graduates, but none should be permitted to practise in the State without first passing an examination before a State board of medical examiners. Thus there would be a uniform educational qualification relating to the branches which are at the foundation of medicine—anatomy, physiology, surgery, and chemistry; while regarding therapeutics and theory there need be no undue restrictions. In thus pointing out the means of effecting the unity of the profession, Dr. Roosa referred only to the State of New York. Speaking of collegiate education, he said he did not believe in exacting a Greek and Latin course, nor in compelling the student to spend too many years at college before entering upon the study of medicine. He believed President Barnard's view would prove the correct one—that in time there should be a few universities or colleges, such as Yale, Harvard, and Columbia, while the many now in existence should be preparatory; and from these, students could pass at once to the medical or law school.

PERISCOPE.

Traumatic Aneurism in a Child.

In the *Indian Medical Gazette* for July last, an interesting case of traumatic aneurism in a child under one year of age is recorded. The patient, a girl, eleven months old, while at play, fell upon the floor, sustaining a bruise on the left cheek, which was followed subsequently by the development of a large pulsatile tumor of the size of a hen's egg. The health of the child in no way suffered from the swelling until one day when she accidentally scratched the skin covering it with her nails; inflammatory symptoms supervened, and a medical man ordered poultices to be applied, subsequently puncturing the tumor. Alarming hemorrhage followed the puncture, which could not be controlled. When Mr. Bose, who records the case, was summoned, he found the child almost bloodless. The dressings were removed from the wound and the clots turned out; the small malar branch of the facial artery was feebly spouting, and was at once twisted. The soft parts around the wound were sloughy. The following morning it was seen that the hemorrhage had still continued; the sloughing process had spread to the outer canthus of the eye. A consultation was held, and it was decided to adopt further measures. The facial artery was tied, the inflamed tissues were freely incised, all the clots were removed, and the wound dressed with boracic ointment. The hemorrhage then ceased, but the child died at the end of three days.—*Medical Press and Circular*, Oct. 10, 1888.

Surgery of Abscess of the Lung and Empyema.

In an address on the surgical treatment of abscess of the lung and empyema, delivered before the British Medical Association, at its meeting in Glasgow last August, M. T. Pridgin Teale spoke of the following points as gradually becoming clear in the surgery of the chest.

1. We are losing our fear of exposing the pleura and the lung, just as we have learned step by step how to deal boldly and safely with the peritoneum.

2. The evil of admission of air into the pleural cavity is not the mere exposure of the pleural surface to the air, is not that the lung collapses by the mere admission of the air, but that where there is a fairly healthy lung and pleura, the inrush of air reduces to a serious extent the mechanical power of the thoracic wall over the function of inspiration.

3. That in cases in which this mechanical difficulty threatens the life or impedes the recovery of the patient, surgery must decide upon the best method of closing the wound to the inrush of air, whilst allowing adequate drainage of any pus cavity to be carried on.

4. That the region of the diaphragm is a situation in which abscess amenable to surgical treatment frequently occurs, such abscesses often commencing below the diaphragm, and tending to discharge through the diaphragm and through the lung.

5. It seems probable that such abscesses can be more safely attacked through the lower angle of the thorax, provided there is dulness at the seat of puncture, than through the abdominal wall

6. As to washing out the cavity of a large pleural, or pulmonary, or hepatic abscess, it is probable that antiseptic washing is of value in the early period, whilst the cavity is offensive ; but that, as soon as the secretion has become sweet, washing is not only unnecessary, but tends to disturb the comfort of the patient, and retard his progress. If drainage is effective, so that fluid does not lodge, the fluid, which is sweet when secreted, should escape from the cavity before it has time to deteriorate

7. As to the question of excision of portions of rib in treating empyema, on this point I am unable to speak from personal experience. The tendency of surgical opinion seems to be rather to reserve it for special and exceptional cases than to make it a general rule of practice.—*British Med. Journal*, Oct. 13, 1888.

Treatment of Diabetes with Large Doses of Codeine.

Bartolomé Novaro (*Deutsche Medizinal-Zeitung*, No. 80, 1888) speaks very favorably of codeine in large doses in diabetes. Of 12 diabetics treated by him with codeine, 7 were cured, 2 improved, 2 died, and in one the treatment was without effect. One of the patients that died had diabetes in a very severe form, and succumbed to pneumonia. As to the method of giving the codeine, he states that fifteen grains of codeine were made up into twenty pills, of which three were taken on the first day. If they were well borne, without headache, immoderate sleep, etc., then on the following day one pill more was given, and if tolerance continued, on the third day still another, so that the patient very quickly reached the daily dose of four and a half grains. This dose was the usual average dose, which was increased or diminished by and bye, according to the tolerance of the patient, to the symptoms produced, and especially according to the quantity of the urine and of the sugar contained in it. He divides the results obtained into three classes: 1. The sugar wholly disappears, and so do the polyuria and the thirst. If this result follows, the author continues the treatment for two or three weeks longer. If no sugar then occurs, the number of pills is gradually reduced by one, until only one a day is taken. Subsequently, this one pill is given only every second, third and seventh day, so that only one a week is taken; and then finally, the codeine is stopped entirely. 2. When the sugar in the urine decreases absolutely or relatively, but the improvement is less perceptible than in the first case, each week the daily number of pills is increased one, to determine the tolerance of the patient. Only in rare cases is it necessary to advance to a daily dose of ten pills (seven and a half grains), as in general the sugar disappears sooner, or some symptoms indicating the point of tolerance occur, which do not permit further increase of the dose. If the patient has completely recovered, he proceeds as in the first case. 3. If neither the sugar in the urine nor the quantity of urine diminishes, the dose of codeine should be increased as long as this is possible.

As to the method of action of codeine, he believes that it checks the increased production of sugar in the human economy through a sedative action, with the aid of the nervous system, upon the glycogenic power.—*Wiener med. Presse*, Oct. 21, 1888.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.00**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PELVIC INFLAMMATION AND ABSCESS.

The present status of this subject is an illustration of the fact that knowledge may be acquired, forgotten, confused, re-acquired and placed on an enduring basis. The conflicting theories as to the relative frequency of cellulitis and peritonitis, of phlegmon of the pelvic cellular tissue and ovary, and of collections of pus within the tubes and the cavity of the pelvic peritoneum, seem destined to early and final settlement.

The Ancients appear to have had no definite knowledge of pelvic inflammation. Puzos, in 1743, regarded it as a milky deposit, a metastasis of milk. Doherty and Churchill, in 1843, wrote on chronic inflammation and abscess of the uterine appendages, without defining the tissues involved in the morbid processes. Marchal, a year later, described the existence of abscesses in the sub-peritoneal connective tissue, sub-aponeurotic space, ovary, and the cavity of the pelvic peritoneum. Noust, in 1850, insisted that all inflammatory swellings in the pelvis were located in the cellular tissue, and that the peritoneum was not involved, and designated the process by the term periuterine phlegmon. Bernutz, in 1857, on the other hand maintained, on the ground of clinical and *post-mortem* evidence, that the pelvic inflammations coming under his observation occurred at the expense of the pelvic peritoneum, and that the cellular tissue was not to any extent invaded. He acknowledged the existence of phlegmons of the broad ligament, but considered that they should be studied with phlegmons of the iliac fossa, of which they form an interesting variety. Bernutz reports thirteen autopsies in non-puerperal women, in nine of whom one or both tubes contained pus; in two of the cases he found tuberculous deposits, and in four the ovaries were healthy. In a number of the cases the tube was adherent to the ovary, the fimbriated extremity occluded and the fimbriæ destroyed; while adhesions were found binding the displaced organs in various relations.

According to Wylie this is the accepted teaching to-day—and it has been made plain in the past two or three years by hundreds of operations for the radical cure of a large class of cases which until recently were regarded and treated as cases of chronic cellulitis. It may be considered as demonstrated that in the vast majority of cases what is known as pelvic inflammation consists in salpingitis with secondary peritonitis and ovaritis, and that this is especially true in women who have not borne children. In some cases the subjacent

connective tissue is more or less involved secondarily; but pelvic cellulitis, pure and simple, is a very rare disease. It occurs most commonly—when it occurs at all—as pointed out by Bernutz, during the puerperium; and it tends to pursue an acute course ending in resolution or abscess. The inflammation is seldom confined to the cellular tissue, but also involves the endometrium, the mucosa of the tubes, and the pelvic peritoneum. It sometimes follows operations on the vagina or cervix uteri; but recent *post-mortem* examinations show that under these conditions the septic inflammation usually spreads through the tubes to the pelvic peritoneum. Cellulitis also occurs as a result of laceration of the cervix, of pelvic hematoma, and of ulceration of the bladder and rectum.

If we consider a collection of pus within the cavity of the pelvic peritoneum an abscess, then, as far as he went, Marchal de Calvi was right in his classification of pelvic abscesses; but if by the same license we consider a collection of pus within the lumen of the Fallopian tube an abscess, he omitted the most common variety, namely, pyo-salpinx. We are aware that some disciples of Tait, especially in this city, go so far as to deny the existence of phlegmon and abscess of the pelvic cellular tissue, and this in spite of the testimony of reliable and trustworthy men, though they admit that, in some cases, the distended tubes rupture into the cellular tissue of the broad ligament, thus forming a secondary abscess. Aside from reliable evidence collected in the past, their claims are refuted by the reports of cases in which laparotomy has been done, and the tubes found healthy, although abscess of the pelvic cellular tissue was present. Such cases have been reported in this city by both Parish and Longaker.

In the light of our present knowledge it seems plain that in cases of so-called pelvic abscess arising independently of puerperal processes, the pus will be found most frequently in the tubes, less frequently in the ovaries or cavity of the pelvic peritoneum; and in rare instances in the pelvic cellular tissue through leakage of pus into the cavity of the broad ligament. This is also true in cases occurring after labor or abortion, but in these cases cellulitis and abscess are far more likely to complicate the salpingitis and peritonitis, and especially so in the virulently septic, fatal cases. Cellulitis and abscess occur after labor and abortion, with slight secondary peritonitis—corresponding to the pleurisy which complicates pneumonia. Cellulitis and abscess occur at times independently of puerperal processes, as a result of hematoma, injuries, ulceration of the bladder and rectum, and some other conditions.

THE TREATMENT OF WOUNDS WITHOUT DRAINAGE.

At the last meeting of the German Surgical Society, Dr. Rydygier, of Cracow, described a method of treating surgical wounds which he has used with great success in his clinic. He devotes great care to the thorough disinfection of the field of operation and of the operator's hands and instruments. He uses only the mildest and most unirritating disinfectant solutions for irrigating the wound, and leaves as little blood behind as possible, not because blood, in itself, does any harm, but because it furnishes too favorable a nutrient fluid for micro-organisms. He sutures the edges of the wound loosely; and covers them with several layers of cheese-cloth impregnated with iodoform or corrosive sublimate, which are soaked in a 1 : 1000 solution of corrosive sublimate and squeezed nearly dry just before their application. In case of operations which create a cavity he next applies carefully graduated compression, with gauze or cotton, so as to reduce the cavity made by the operation to the smallest size possible, and ends with a dry dressing.

This method is only applicable to cases

in which union by first intention may be reasonably anticipated; but Rydygier has used it in forty major operations with very satisfactory results. In six cases union by first intention did not follow; but the patient did not suffer any harm, and it only became necessary to resort after all to drainage.

It is interesting to note in many of the attempts which have been made of late, especially in Germany, to simplify the treatment of wounds, that the most successful efforts have been in the direction pointed out by that clear-headed man and excellent surgeon, the late Mr. Sampson Gamgee. Before the day of the spray and carbolized dressings, Mr. Gamgee, and those who fully understood the principles of his methods, obtained the most admirable results in the treatment of surgical wounds with what he described as graduated compression, and dry and infrequent dressings. It is our conviction that much of the success of modern surgery is attributable to an unwitting application of the principles which he believed in so firmly and advocated so warmly, and that the most important details of the so-called antiseptic methods are those which are in harmony with these principles. This opinion may seem to be at variance with the impression created by the details of certain very successful methods, in which there is very little appearance of dryness; but on analyzing them it will be seen that the lavish use of fluids which they require does not in the least affect the principles which Mr. Gamgee advocated. The profuse washing of wounds, where fluids are most freely used, is but preliminary and preparatory to the dry and infrequent dressings which follow; and abundant experience demonstrates the fact that when fresh-cut surfaces have been made surgically clean the best results may be obtained by imitating Nature's method of sealing up a wound with a blood-crust, and letting it take care of itself.

This is the principle which underlies many of the most recent efforts to simplify the treatment of surgical wounds, and it seems worth while to direct attention to this fact as we record their successes, and recommend them to the notice of our readers.

LICENSE TAX ON PHYSICIANS.

It is reported that the City Council of Salt Lake City has recently ordered a license tax to be imposed upon all persons practising medicine in that place. This action has very naturally excited opposition on the part of the physicians, and they have presented a temperate remonstrance, which contests the argument that the tax will tend to elevate the standard of medical practice.

The Salt Lake Medical Society voices the sentiment of the medical men of the city in stating that a license tax is about the worst scheme which could be devised for this purpose, as it substitutes a money consideration, which none could furnish more easily than unscrupulous pretenders, for a test of mental and moral fitness which would debar them from practising.

In this the Salt Lake Medical Society is altogether right; and it is hard to understand how any intelligent body of legislators could be led astray from such sound principles, and how it could overlook the fact to which the Society calls attention, that it is entirely unjust to impose a special tax upon a class of men who do so much charitable work, and who are so serviceable to the public.

It is unfortunate for physicians that nowadays the practice of medicine is often regarded as a business, instead of a vocation, and that the ancient respect for our profession has largely disappeared. This is due in part to the freedom with which medical men have communicated information peculiar to their calling to the public, and in part, we believe, to the commercial spirit which is sometimes displayed in doing so. The action of the physicians of Salt Lake City attracts attention to this feature of the

present position of medical men, and prompts the thought that our profession would be in less danger of hostile criticism and unfair treatment if it were wholly free from conduct which detracts from the standing it once had, and brings it into the category of business-men. Let us all think about this, and see what we can do to regain what we have lost. While we join our protest to that of our brethren in Utah against any attempt to impose unjust restrictions upon those who are engaged in the work of healing, let us also labor to maintain a standard of character and educational fitness for our work which shall merit and secure the confidence and respect of our fellow-men.

SEWAGE DISPOSAL.

The problem of the proper disposal of sewage is one of the most important which confronts sanitarians, and every intelligent attempt at its solution deserves careful study. For this reason we call attention to the system of works recently completed in the township of East Orange, N. J., which is practically a suburb of New York City.

The plans for this system were designed about two years ago by Mr. Carroll Ph. Bassett and Mr. Rudolph Hering. The whole includes a series of pipes to receive the sewage and convey it to the works, and the works themselves where the solid matters are separated from the liquid by a combination of precipitation and filtration. The manner in which this is done is described, with illustrations, in the *Scientific American*, Nov. 17, 1888.

The process consists in adding to the whole mass of sewage successive quantities of milk of lime and sulphate of aluminium. These two substances react so as to form sulphate of lime and alumina, and in falling they carry down the solid matter which was held in suspension in the liquid sewage. The whole of the sewage is conveyed into a main and two tanks of peculiar construction, in which the work of precipitation is carried out so that it results in separating a pultaceous mass and a clear liquid. The former is pumped into vacuum pans and forced by pneumatic pressure into filter presses, where clear water passes out and hard cakes of solid residue remain behind. The filtrate, as well as the supernatant clear liquid which passes off from the precipitating tanks, is carried by pipes to a field where it is applied to improve the soil; while the solid cakes are expected to have a high commercial value for fertilizing purposes.

The coming winter will test the capacities of this system, which is so admirable in theory, and by the end of a year we may expect to have its results demonstrated in a way which cannot but prove instructive to all who are interested in this important phase of town sanitation.

There can be no doubt, we think, that some such system for the disposal of sewage is the only rational one; for those which consist in merely carrying off the refuse of towns and cities and emptying it into a flowing stream are mere expedients, and are open to many theoretical and practical objections. It will be of especial value if the experiment at East Orange should prove remunerative, by increasing the value of the products of the farm connected with the works, and from the sale of the fertilizer made in them; for this would simplify very materially the problem of applying the same system to other towns and cities That this may be the case must be hoped by all sanitarians, who for their own sakes will wish the greatest success to the enterprise which we have just described.

—A plumber in this city who had neglected to obey the law which requires him to submit plans of plumbing work to the Board of Health for approval, and had also neglected to report what he had done that it might be inspected, was fined fifty dollars. The Court also gave the wholesome admonition that, in future, offenses of this kind would be more severely dealt with.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A SYSTEM OF GYNECOLOGY BY AMERICAN AUTHORS. Edited by Mathew D. Mann, A.M., M.D., Professor of Obstetrics and Gynecology in the Medical Department of the University of Buffalo, N. Y. 8vo, pp. 1180. Illustrated with 4 colored plates and 361 engravings on wood. Philadelphia: Lea Bros. & Co., 1888.

This volume, which completes the work on gynecology, is made up of the following papers: The Diseases of the Vagina, by Charles Carroll Lee; The Hystero-Neuroses, by George J. Engelmann; Extra-Uterine Gestation, by T. Gaillard Thomas; Tumors of the Breast, by Samuel W. Gross; Diseases of the Breast Other than Tumors, by Roswell Park; Fistulæ, by Edward W. Jenks; Diseases of the Bladder and Urethra, by William H. Baker; Non-Malignant Tumors of the Uterus, by R. Stansbury Sutton; The Malignant Diseases of the Uterus, by W. T. Lusk; Lacerations of the Cervix Uteri, by Bache McEvers Emmet; Chronic Inversion of the Uterus, by Samuel C. Busey; Injuries and Lacerations of the Perineum and Pelvic Floor, by Howard A. Kelly; The Treatment of Ovarian and Extra-Ovarian Tumors, by William Goodell; Diseases of the Ovaries, by Robert Battey and Henry C. Coe; Diseases of the Fallopian Tubes, by Henry C. Coe and W. Gill Wylie; The Pathology of Ovarian Tumors, by Stephen Y. Howell; The Clinical History and Diagnosis of Pelvic Tumors Other than Uterine and Tubal, by Matthew D. Mann; and Displacements of the Uterus, by George T. Harrison.

A glance at these subjects shows several novel features. Chapters upon the hystero-neuroses, diseases and tumors of the breast, and diseases of the bladder and urethra are well worthy of a place in a modern treatise on gynecology. This volume deals with those subjects which recently have agitated the profession. We will note the treatment of some of them:

Owing to the extensive experience of its author, the article on Extra-Uterine Pregnancy, by Thomas, is especially welcome. He practically agrees with Mr. Tait as to the primary location of extra-uterine pregnancy in the tube—emphasizing the fact "that prior to the twelfth week of gestation the fœtus is very apt to be found in the Fallopian tube"—yet he retains the accepted classification. The author's treatment is conservative. After rupture of the sac, extirpation by laparotomy is not advised in all cases. "During the profound shock which very generally attends such rupture, operation is, of course, impossible." Expectancy is advised, and we are to wait for further evidences of hemorrhage, peritonitis, or septicæmia. In this particular we believe the author is not in accord with the current belief. Why should hemorrhage from a ruptured ectopic pregnancy be an exception to the recognized surgical rule, that hemorrhage must be arrested (except, of course, in those extreme cases in which any effort would simply precipitate the inevitably fatal end)? Should the diagnosis be pretty certain (before the period of viability), and rupture, as indicated by symptoms and signs, imminent, and skillful surgical and nursing aid available, laparotomy and exsection of the sac is advised—or, if exsection is impossible, stitching of the sac in the abdominal incision, with drainage. Should these conditions not be present, fœticide is indicated, by Faradism or galvanism, and extirpation only attempted should subsequent events demand it. The treatment after fœtal viability is also considered.

Sutton gives a good exposition of the subject of Non-Malignant Tumors of the Uterus. We cannot consider the section on treatment, however, as complete. The statistics of the results of operative methods are only brought up to '82–'84, and no mention is made of Thomas Keith's changed views as to the justifiability of hysterectomy. No opinion is expressed as to the value of electrolysis in the treatment of fibroids; we are simply referred to the article by Rockwell in Vol. I. The author concludes that fibro-cystic tumors should be removed, but not necessarily the solid tumors; that removal of the uterine appendages for fibroid tumor is unjustifiable when the tumor can be removed per vaginam; that removal of the appendages is especially indicated in small non-cystic fibroids; that probably 29 out of 30 cases should not be operated upon, as the symptoms do not justify operation. These views are sound, but we believe that the indications for electrolysis should have been defined. Lusk gives an admirable presentation of the subject of the Malignant Diseases of the Uterus, together with the methods of treatment. He says that whether or not a cure can best be accomplished by hysterectomy, or if, in selected cases, partial ablation furnishes a safer and equally satisfactory procedure, is still *sub judice*. The various methods of treatment are well presented. The articles on Neoplasms of the Tubes, by Coe, and on Salpingitis, by Wylie, are welcome additions to the literature. Wylie accepts the results of "Bernutz's remarkable researches on the nature and pathology of pelvic inflammations. He clearly described the disease clinically, and he showed, pathologically, that it was a disease of the tubes and ovaries, accompanied by peritonitis, and that cellulitis had no influence in causing the symptoms, and that it rarely existed except as a phlegmon in puerperal cases. This is the accepted doctrine of to-day—in the past two or three years made plain by hundreds of operations for the radical cure of that large class of cases until recently regarded and treated as pelvic cellulitis."

The student will be confused by conflicting statements made by the various authors—for example, as to the nature, relative frequency, and importance of cellulitis and peritonitis. Also, there is more or less overlapping—thus Emmet's operation for procidentia is described and figured twice, and his operation for narrowing the vaginal outlet is figured twice and described three times; twice the description is copied from his work, which, as is well known, was never intelligible to anybody, and fortunately, the third time, it is described by Kelly in such a way as to be understood.

The two volumes form a most excellent treatise on gynecology, and reflect credit alike on the editor, the authors, and the profession in America. From the standpoint of the therapeutist, we believe it has no superior.

—Surgeon William J. Simon, of the United States Steamer Boston, died of yellow fever on board that vessel at New York, Nov. 27. The other yellow fever patients on the vessel are said to be steadily improving.

CORRESPONDENCE.

The Congress and the Journal of the Association.

TO THE EDITOR.

Sir: In a recent issue of your valuable journal, you called attention to and made some just comments upon a letter which was published in the *Journal of the American Medical Association*, issue of Sept. 22, 1888.

The letter, from which I make the following extract, was *unsigned*, simply headed "From a London Correspondent." Whether written in this country or in London, its ear-marks justify the belief that the London correspondent is no other than a certain American who covers up his identity whilst he makes a stab in the dark. He writes:

"The meeting this month in Washington of the Congress of American Physicians and Surgeons has made little or no impression upon the mass of medical men throughout Europe. Now and then I have heard reference made to the meeting in a kindly manner in this and other medical centres. A very large number of eminent members of the profession in all parts of Europe have been invited, and were urged to attend, but few, very few, will be at the meeting, even though I am told that suggestions have been made to many that possibly American degrees may be conferred upon many who will honor them by their presence.

"Unfortunately for the present managers of the Congress, the part they have taken during the past year against their own countrymen has now become more apparent here, and the reaction has been anything but favorable to them and their meeting. The suggestion, or even the promise, of degrees to be given out, which is whispered around here, may induce a few to attend the meeting, but the very many invited will stay at home"!

Intimately acquainted as I am with the whole scheme of the Congress from its inception to the present moment, and having done by far the largest amount of its foreign correspondence, I am fully and entirely prepared, and that too without fear of contradiction, to say the charge made against "the present managers of the Congress," of suggesting or promising that American degrees would be conferred upon anyone who would honor them with his presence, is without foundation and absolutely *false!* No such idea ever entered the brain of any one of us, and it is supremely ridiculous for anyone to suggest the bare possibility that such distinguished gentlemen as we did invite to be present could be caught by any such bait as a college degree! To stamp the charge as untrue, it is well understood that the Congress itself has no power to confer degrees; and since it was not managed in the interest of any institution having such powers, it was not within the ability of its managers to make any such offer. The letter in question is simply a gratuitous insult to the gentlemen engaged in organizing an association purely scientific in its purposes and without opposition to any existing organization.

As the letter was without signature, thus indicating it to be from an irresponsible party, it would never have received any notice, had not the following "extract" from a foreign periodical been sent me. This shows the *real impression* which the Congress has made upon distinguished gentlemen abroad:

"It is the opinion of those well able to judge that the meeting of this Congress has been a great success in every way. The papers and discussions have been of a very high order, and the visitors are unanimous in considering that there are men in the medical profession of America of the highest culture, ability, and scientific spirit, all of whom are doing work of great value and importance; and it is also markedly evident that there is every desire and determination on their part to raise the character of medical education in their country. In fact, members of the profession in all countries, who wish to keep themselves thoroughly acquainted with all recent and important medical and scientific improvements and suggestions, must carefully study what is being done in America, otherwise their knowledge will not be complete; and I venture to predict that the professional centres and their institutes in this country will in the future be largely visited by those who desire to *perfect* their knowledge of science and medicine."

The letter enclosing this clipping closed as follows:

. . . "I enclose this cutting from an article upon the Congress printed in our principal Scotch paper, 'The Scotsman.' It expresses my own opinion on its success. With kindest regards I remain, very truly,

Thomas Annandale."

Is it reasonable to suppose that such

distinguished gentlemen as Mr. Thomas Annandale, of the University of Edinburgh, Sir William MacCormac, of London, Prof. Fred. Von Esmarch, of Kiel, together with others equally distinguished, who were present at the Congress, were "the few who were induced to attend the meeting with the expectation of receiving American degrees"?

Yours truly,
CLAUDIUS H. MASTIN.

Mobile, Alabama,
Nov. 22, 1888.

Physicians and Druggists.

TO THE EDITOR.

Sir: You will remember that when we last met I suggested to you the discussion of the relations between the Physician and Druggist, and that I asked you what was to become of the practising physician in towns ranging from a very few hundred inhabitants (but thinking itself large enough to support one or two drug-stores) up to the larger towns and medium-sized cities, wherein apothecaries do much abound.

I believe it is not considered quite the style now for a physician to carry his own medicines. The druggist has his eye upon all such, and if he should be a man of much importance either in the trade or socially, and whenever opportunity offers, the poor doctor gets a black eye, and a reputation slightly depressed in every encounter with the learned counter-prescriber.

What does the Physician owe the Druggist? It is admitted that the latter shall keep a supply of the remedies needed in the community—physicians in the towns and villages can scarcely be expected to keep everything needed. The druggist is thus far and in proper bounds a necessity in the community. It is generally expected that the Physician pays at least 25 per cent. for such articles as he wants. This is enough. What obligation is the practitioner under to prescribe all the time when he sees the Druggist's counter and shelves loaded with all the proprietary articles ever heard of, with their all-healing virtues duly inscribed upon the wrappers? When he learns that the druggist soon acquires the name of Doctor from the facility with which he recommends and prepares medicines for his customers, is the sense of indebtedness heightened?

I may be called an old fogy, but I believe the physician, be he located in city, town, or country, should carry and dispense the most of his medicines. Why? I answer:

1. The man who is constantly handling his own drugs learns more about them. I have seen doctors so ignorant of the appearance, taste and smell of many useful drugs that they could not have told whether they had what they wanted or not. This should not be.

2 The expense. If all our patients were rich and generous, this argument would be needless. But there are thousands unable, when sick, to pay the Doctor 1, 2 or 3 dollars for an examination and a prescription to the favorite Druggist, which, when duly prepared, will cost a dollar or two more (especially if there has been a contract between apothecary and Doctor to divide). I say they can't pay both. If the Doctor is not soulless (and I pity a soulless Doctor) he loses: the money goes to pay for the medicines.

3. Old practitioners able to do the best work and turn undesirable calls away can get along; but how can the young physician, who has expended most of his earthly goods to get his Degree of M.D., make headway until he can get established, with the old Doctor and the Druggist both against him. The old Doctor is loyal to the Druggist; has grown fat and indolent. The Druggist cannot desist from whispering across the counter, whether asked or not (often his opinion is solicited before the Doctor is sent for), that it would never do to drop old Doctor Bolus. (I reverence the old as much as others.) What is the young Physician to do? What wrong is he doing if he examines a patient and gives him or her such medication as may be required and collects one dollar or more or less, as the case may be, for advice and medicine? If the patient has to pay the young professional man as large a fee as the older and well established one charges, why, often the young man will starve or go to some manual labor.

Now, Mr. Editor, tell me why it is wrong to do this. I need not tell you that the success of Homœopathy is due to this one fact, that the Doctor carries his medicines. Manufacturing chemists in your city and elsewhere are making such preparations that the Physician can carry his own medicines conveniently and save many an honest penny; and I believe it would be to the advantage of many a doctor, and often to the patient's advantage also, if he were to avail himself of these preparations, and dispense his own drugs. Yours truly,

OLD FOGY.

The Prevention of Conception.

To the Editor.

Sir: In initiating the discussion on the Prevention of Conception, I was careful to state my position distinctly and in plain language. I denounced criminal abortion, and noted my objection to craniotomy during parturition. I have never in the past interfered with conception to save life (as in irrepressible vomiting of pregnancy) nor induced premature labor at any period to facilitate delivery, and if such are needed hereafter another physician must take the case.

In my paper throughout, the question was considered in its connection with the married state alone. The regulation of conception under "proper conditions" was my theme, and I therefore object to Dr. Pierce's assuming, as he does in the issue of November 17, that I countenance immorality in any degree; and those who criticize aside from my standpoint have no right to quote me at all. I am opposed to adultery and prostitution, and although I look with contempt on the bigotry apparently inseparably connected with the discussion of medical problems by so-called religious persons, in this one I am thoroughly orthodox. The eminent physician referred to by "X. Y. Z." in the Reporter of the 10th inst. must hold peculiar views concerning the etiology of nervous prostration when he advises withdrawal; for all neurologists know that this sexual fraud is eminently productive of both local and constitutional disorder, severe in type, *but invariably in the woman!* As to the man, the loss of semen in excess is the factor causing debility or reflex trouble, and not the manner of terminating copulation or of producing emission. The intercourse should always be normally complete, and the use of all mechanical shields, sheaths, etc., by either sex, should be prohibited. It is probable that in most females a longer or shorter intermenstrual period exists during which fruition succeeding sexual congress is not likely to occur, and by observing this and suggesting subsequent ablution the physician will, in the case of those entitled to advice, do all that is required of him. It is difficult to particularize even in a medical journal, without allowing matters to get beyond professional bounds, hence I do not care to say more.

Yours truly,
W. R. D. Blackwood, M.D.

246 North Twentieth Street,
Philadelphia.

Notes and Comments.

A Thirty Days' Fast in Edinburgh.

Alexander Jacques, a Frenchman, has lately begun a thirty days' fast at the Douglas Hotel, Edinburgh, his object being to demonstrate the utility of a certain herb, which he asserts has unusual sustaining and nourishing properties. He has been offered $3000 for his secret, but declines to reveal it under $100,000. The plant, which he says is quite a common one, supplies him with a powder which he calls "Sauveur," and this powder, he holds, will sustain the body in health and comparative vigor without any nourishment being taken, for a time not yet decided. His experiment is exciting considerable interest, and a large number of medical men have visited him at the Douglas Hotel. M. Jacques is, of course, being closely watched, the vigilance committee consisting of medical students, who take the deepest interest in the demonstration. Except for a walk in the early morning, M. Jacques never leaves the hotel. An occasional pinch of his powder, some mineral water, and cigarettes are all he has indulged in since the experiment began, now more than a week ago. He is quite cheerful, and seems confident that he will be able to complete his experiment.—*Medical Press and Circular*, Nov. 7, 1888.

Antipyrine in Polyuria.

At the meeting of the Kansas City Medical Society, October 4, 1888, Dr. Hereford made a verbal report of his own case, and the accidental discovery of the effect of antipyrine in polyuria. He had been affected for some time with polyuria, or diabetes insipidus, and had been unable to find anything which would control the excessive secretion of urine until last August, when, suffering much pain from a carbuncle, he took ten grains of antipyrine for its analgesic effect. It not only quieted the pain, but checked the polyuria. That this was not an accidental arrest of secretion on the part of the kidneys has been conclusively proved by the fact that, since the first of August, he has taken six grains every four hours, and the polyuria is completely under control. No bad effects have been noted under this continuous administration during two months. It probably causes this effect by reducing the irritation in the cerebral center that presides over the secretion of urine.—*Kansas City Medical Index*, October, 1888.

Labor at Full Time; No Rupture of the Hymen.

Hugh Taylor reports the following case in the *British Medical Journal*, November 3, 1888: "Some time ago I was sent for in a great hurry, to a woman in her confinement. She had been in labor for a considerable time, and the midwife told me that there was something which prevented the head of the infant from passing out of the vagina. I examined her carefully, and found a large semilunar-shaped, tough membrane, stretching quite across the lower two-thirds of the vaginal outlet, against which the head was being very strongly pushed by strong uterine action. With some considerable difficulty I was enabled to slip the membrane clear of the child's head, and the labor was then soon completed. The case seems to me of great interest in a medico-legal point of view, as showing that it is quite possible for a child to be born without a rupture of the hymen taking place, and that, therefore, non-rupture of this membrane is not a trustworthy sign of penetration (not) having taken place in cases of rape, etc."

Traumatic Peritonitis; Recovery.

In the *Canadian Practitioner*, November, 1888, Dr. J. J. Cassidy reports a case of severe bicycle accident, followed by peritonitis, hæmaturia, and recovery. The patient was a young man, 25 years old, who fell from his bicycle in such a way that the umbilical and left lumbar regions of the body came in contact with the road. He was severely shocked, so that he was unable to speak. He was, however, able to walk a mile to his lodgings. Peritonitis with hæmaturia developed and persisted for some time, but recovery finally occurred.

North Texas Medical Association.

The North Texas Medical Association will meet in Sherman, Texas, Tuesday, Wednesday and Thursday, December 11, 12 and 13, 1888. In addition to the papers already on the programme to be read in the sections, many valuable volunteer papers have been promised. It is characteristic of this Association that but few minutes are required for the transaction of its general business, the remainder of the time being devoted to scientific section work.

J. T. Wilson, M.D., is President, and George R. Clayton, M.D., Secretary, of the Association.

Dental Department of Meharry Medical College.

The corner-stone of the building to be used for the Dental Department of Meharry Medical College was laid at Nashville, Tenn., Oct. 23, 1888 The Meharry Medical College, which is now attached to the Central University of Tennessee, is intended to give the colored people of the South a more thorough knowledge of the medical and dental sciences. It is the intention of the Faculty to add also a Pharmaceutical Department, the need of which has been frequently manifested by calls upon the institution for educated colored pharmacists. With the exception of the Howard School in Washington, which is for white and colored, there is no other medical school for colored people in the United States.

Prize for Medical Microscopists.

In behalf of "The American Association for the Study and Cure of Inebriety," the sum of One Hundred Dollars is offered by Dr. L. D. Mason, Vice-President of the Society, for the best original essay on "*The Pathological Lesions of Chronic Alcoholism Capable of Microscopic Demonstration.*" The essay must be accompanied by microscopic slides to demonstrate the conditions discussed. Accurate drawings or microphotographs of the slides are desired. Conclusions resulting from experiments on animals will be admissible. The essay, microscopic slides, drawings or microphotographs are to be marked with a private motto or legend and sent to the Chairman of the Committee on or before October 1, 1890.

The essay must attempt to demonstrate: *First*, Are there pathological lesions due to chronic alcoholism? *Secondly*, Are these lesions peculiar to chronic alcoholism?

The microscopic specimens must be accompanied by an authentic history of the case; and complications, such as syphilis, should be excluded.

The successful author will be promptly notified of his success, and asked to read and demonstrate his essay personally or by proxy, at a regular or special meeting of the "Medical Microscopical Society" of Brooklyn. The essay will then be published in the ensuing number of *The Journal of Inebriety* (Editor, T. D. Crothers, Hartford, Conn.) as a Prize Essay, and then returned to the author for further publication or such use as he may desire. The following gentlemen have consented to act as a Committee: John E. Weeks, M.D., Richmond Lennox, M.D., W. H. Bates, M.D., Chairman.

NEWS.

—A heavy frost occurred at Jacksonville, Fla., Nov. 25, and has given occasion for great rejoicing among the people.

—It is reported that Dr. Henry D. Nicoll has been appointed to the Woman's Hospital, New York, succeeding Dr. T. Gaillard Thomas, who has resigned.

—An association called "The Physical Education Society of Pennsylvania," has recently been organized in this city. Dr. A. H. P. Leuf was elected President.

—Typhoid fever is reported to be epidemic at the McAllisterville Soldiers' Orphans' School. Thirty cases and one death are said to have occurred so far. There are nearly two hundred boys and girls in the school.

—From January 1, 1885, to Oct. 9, 1888, the Medical Examining Board of Virginia has examined 240 applicants for license to practise in Virginia; of this number 54 were rejected on first application, and 10 on the second application, while 5 examinations are incomplete by withdrawal of the applicants or otherwise.

—For the week ending Nov. 13, there were 139 cases of scarlet fever in New York and 28 deaths; and during the same period, 136 cases of measles and 11 deaths. During the week following (ending Nov. 20), there were 130 cases of scarlet fever and 2 deaths; while the number of cases of measles had increased to 221, but no deaths were reported.

—In the *Weekly Medical Review*, Nov. 17, 1888, Dr. Ap. Morgan Vance communicates the notes of a case of a mulatto girl, three and a half years old, who was born with a tail. There was no bone in it or prehensile power; it was exactly like a small pig's tail. At birth it measured one inch and a-half, and when removed it was four inches long.

—The *Lancet* says that Sir Morell Mackenzie has resigned his membership in the College of Physicians. This action seems to have been taken because at a Council Meeting of the British Medical Society a resolution was passed deprecating the publication of the details of the late Emperor Frederick's illness as a violation of professional confidence. The Council accepted the regrets of the editor of the *Journal* concerning the publication of them.

HUMOR.

A LARGE IRON SPRING has been discovered in the northern part of the State; it is supposed to have escaped from a Waterbury watch.—*Life.*

IN HIGH CIRCLES.—First Tramp—"I say, have you taken a bath?" Second Tramp (anxiously) — "No! Is there one missing?"—*Harvard Lampoon.*

"DEAR MR. EDITOR: Please read the enclosed poem carefully and return it to me with your candid criticism as soon as possible, as I have other irons in the fire." "Dear Mr. Smith: Remove the irons and insert the poem."—*Journalist.*

TRAMP (coughing)—"No, mum, my health ain't none of the best. I've had this cough two years." Woman—"Why don't you do something for it?" Tramp—"Well, mum, my family doctor died yistiddy, an' I hain't seen a physician to-day what I'd like to trust my health with."—*Time.*

A BRILLIANT SUCCESS.—"Just try to frighten me, will you?" said B—— to M——. "What for?" "I have got the hiccough, and if you frighten me it will make it go away at once." "Very well, then; here goes" (shouting at the top of his voice): "Lend me five hundred francs!" "Ah, thanks! it is gone!"—*Figaro.*

A PECULIAR CASE OF FRACTURE.—He had been in the habit of playing truant from school, and he had been moderately lucky in getting out of the scrape. But he was caught one day and brought before the teacher. "You're late. Where have you been?" "I've been sick." "You don't look sick." "Well, I'm better, but I've been sick, all the same." "You go right home and get a note from your mother or I'll punish you severely." He went off and was gone about ten minutes. It was pretty quick work, and when he handed the note to the teacher she thought that the handwriting did not look like his mother's. She kept her eyes on him as she opened the note, but he was as bland and as innocent as the best boy in the world. The note read: "Miss ——: Please excues John this mornin fur bein late, cos he broke his leg. MRS. ——."—*San Francisco Chronicle.*

DIED.

At the residence of her husband, Darlington, Maryland, on November 18, 1888, of typhoid fever, ADDIE FORWOOD, wife of Dr. W. Stump Forwood, aged 53 years.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Our New Lens Front, or Magnifying **Clinical Thermometers**, with **Indestructible Register** and **Ineffaceable Scale**, are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

Clinical Lecture.

BASAL MENINGITIS.

BY LANDON CARTER GRAY, M.D.,

PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE NEW YORK POLYCLINIC.

Gentlemen: I shall read to you the history of a very interesting case of intracranial lesion:

Miss ——, forty-three years old, has all her life been troubled with weak eyes, her family being all near-sighted; but about five or six years ago she began to suffer with severe headache, and soon afterward observed that her eyes were failing more than had been the case with any other member of the family. She has never at any time during her life been much of a reader, because of the weakness of her eyes. Last September the eyes became very much worse, so that she sought the advice of a well-known oculist. At that time she had temporal hemianopsia of the right eye in a vertical meridian. In the left eye a zone of diminished vision went five to ten degrees farther to the right side. Her sight was in the left = 1/8. Since that time the patient has become rapidly worse, so that the right eye, she tells me, is completely blind, whilst the left is almost so. The headaches have become much more severe. When she first came to me, February 4, 1887, she could distinguish the gas flame, and could tell that I had lifted up my arm between her and the light; but she could distinguish nothing more definitely. There was slight external strabismus of the right eye. The left eye was completely blind. The senses of smell, taste, and hearing were distinctly impaired on the left side, whilst the same senses were perfectly normal upon the right. The hand-grasp on the right was distinctly weaker than on the left. There was a slight difference in strength between the right and left legs, the right being the weaker. She told me that she was much weaker on the right side after a severe headache, that she would then stagger to the right, and that this weakness would persist for several days after an attack of headache. She also says that at the time of the special weakness of this right side she has dull aching throughout it. The headaches come with great suddenness, without the slightest apparent cause, and are accompanied with explosive vomiting; she may, perhaps, have one after a meal that has been eaten with perfect comfort. These headaches come every week or every few days, lasting several hours. There was absolutely no impairment of the senses of touch, temperature, pain, or of the muscular sense on the right side. The tendon reflexes were normal. She walked perfectly well, had no impairment of memory or of intellect, was a very intelligent woman, and in excellent general condition.

Upon this history, obtained over a year ago, I made the diagnosis of a lesion at the base of the brain. It was not a difficult matter to make a diagnosis of an intracranial lesion: the peculiar headache of the so-called cerebral type—*i. e.*, with explosive, seemingly causeless vomiting—and the hemianopsia; the impairment of the three special senses of taste, smell, and hearing, and the motor weakness of the right side after the headaches, constituted

ample data upon which to make a perfectly certain diagnosis of an intra-cranial lesion. It seems almost idle to say that a headache from extra-cranial causes would very seldom have this cerebral type; and, even if it did, it would not be accompanied by all the sensory and motor impairments that were present in this case. Occasionally, it is true, we meet with sudden vomiting in headaches due to nephritis, or in cases in which the urine may be found to be loaded heavily with uric acid crystals; but these cases have, of course, no motor or sensory paralyses. Nor was the question of localization of the lesion a difficult one. The cross-paralysis—*i. e.*, the paralysis of hearing, taste, and smell on the left side, and the motor paresis upon the right side—showed that the lesion must be at the base of the brain, implicating the nerves of smell, hearing, and taste on the left side and the crura cerebri on the same side. As you know, of course, the three nerves of smell, hearing, and taste would be distributed to their respective sense organs upon the same side, whilst the fibres in the crura cerebri would pass over to the opposite side when they had reached the region of decussation in the cord.

But there was, you will remember, external strabismus of the right eye, which means that there was paralysis of certain fibres of the right third nerve, or motor oculi; so that the lesion must have extended to the right side of the base of the brain, although it was mainly located upon the left. The nature of the lesion was not so easily determined. We should have to select, as the most probable causes, either intra-cranial syphilis, a tumor, or meningitis either of idiopathic, traumatic, or middle or internal ear origin. Intra-cranial syphilis was promptly excluded for several combined reasons: 1. The patient was an old maid of irreproachable life and habits; 2. Even admitting that life and habits count for nothing, or that the patient might have been inoculated through some buccal lesion, or in some other accidental way, the symptoms did not indicate any intra-cranial specific infection. As I have had occasion to demonstrate, intra-cranial syphilis has generally very well-marked symptoms of its own, consisting of a headache which has some quasi periodicity, and is often nocturnal; an obstinate insomnia going hand in hand with the headache; a distinct mental irritability accompanying the headache and the insomnia; and, finally, a remarkable cessation of the headache when a paralysis makes its appearance. As none of these symptoms were present in our patient, intra-cranial syphilis could be very certainly excluded.

The diagnosis, therefore, lay between meningitis of idiopathic, traumatic, or of middle or internal ear origin, or a tumor. There was absolutely no history of any trauma, and the most careful examination of the ear disclosed no other disease than that of the nervous apparatus on the left side, which has been described; nor was there any history of any ear trouble in the past. The diagnosis, therefore, still further narrowed itself down to a meningitis of idiopathic origin or a tumor. The neuro-retinitis was, of course, of no diagnostic use, because it might have been produced by either intra-cranial syphilis, tumor, or meningitis; and although there are differences in the early stages in the neuro-retinitis of these three different forms of intra-cranial trouble, no differences were apparent at the stage when our patient first came under observation. The space over which the lesion extends is a matter of considerable importance in the differential diagnosis. In this case, for instance, as you can see by any anatomical plate of the base of the brain, the lesion extends from the olfactory nerves backward to the crura cerebri, and still further back to the auditory and glosso-pharyngeal nerves on the left, and then it also affects the third nerve upon the right side. A meningitis, especially of the pia mater, would be much more likely than a tumor to cover such an extended area in so fragmentary a manner. A neoplasm, too, would have been much more likely to have caused more destruction and to have given rise to a large amount of mental hebetude if it had existed for so long a time and had spread over so wide an area.

A diagnosis was made of a meningitis, probably of the pia mater—a so-called lepto-meningitis—of the base of the brain. The prognosis was regarded as very serious; indeed, the patient's friends were told that, in all probability, death was merely a question of time. The patient was treated simply by means of the iodide of potash, given in increasing doses until forty grains were given three times a day; at times the inunction of mercurial ointment was ordered.

I lost sight of the patient until to-day (April 15), which is about one year after her first visit to me, and six or seven years after the beginning of her cerebral symptoms.

Now let us see what difference in symptoms there is.

She cannot see this gas flame, but she can see me between her and the window. Her sight is, therefore, slightly worse than it was a year ago. Let us test her sense of smell with the oil of thyme. As you know, a distinction must be made between the pungent odors, such as aromatic spirits of ammonia, which are perceived by the sensory filaments of the trigeminus in the nostril, and the pure odors, of which perception is gained through the olfactory nerve. Tested with this oil of thyme, therefore, we find that the sense of smell is now perfectly equal on the two sides, so that the impairment of smell on the left side has entirely disappeared.

We usually test the sense of taste by means of bitters, acids, and salts, using quinine as the type of the bitters, vinegar as the type of the acids, and common table-salt as the type of the salts. Then, again, it must be remembered that the nerve of taste in the anterior portion of the tongue is the chorda tympani, whilst in the posterior portion of the tongue it is the glosso-pharyngeal; so that these anterior and posterior regions must each be examined. The testing of taste is a very delicate matter, and often unsatisfactory with these tests. The best way is to have a little rod or match, with a small piece of absorbent cotton on the end. Dipping this into the test fluids, a drop should be placed carefully first on one side of the median line, and then upon the other, of the part of the tongue to be examined. Before doing this, however, the patient must be instructed to protrude the tongue, and to indicate when he tastes anything, by raising the hand; for, if he attempts to tell his sensation by speech, in goes the tongue, and the testing fluid is smeared all over the buccal cavity and the other portions of the tongue. But the best method of examination of the sense of taste is by the galvanic current. Only a few cells of any ordinary battery are needed, and the ends of the wires should be armed with long metal points. The strength of the current should first be tested upon your own tongue, so as to obtain only enough to give a savor and not enough to burn the tongue; these two metal points should be placed half an inch apart upon the portion of the tongue to be tested, and the patient instructed as before to indicate the presence of the sensation by uplifting the hand. Tested by all of these methods, we find that the sense of taste in our patient is still slightly impaired in the left anterior portion of the tongue, but that it is perfect in the left posterior portion; whereas it was entirely lost both anteriorly and posteriorly a year ago.

The strength of the hands is usually tested by means of the so-called dynamometer, with which all are familiar. But the neurologist comes to have a *manus erudita*, akin to the *tactus eruditus* of the gynecologist. Anyone can attain to considerable skill in the appreciation of strength in a hand-grasp when the matter has been studied through many years and in a long series of patients. I think I can tell the difference between the strength of hands as well with my hand as with a dynamometer. Tested by the hand and by the dynamometer, our patient is found to be equally strong on the two sides, so that the weakness of a year ago has disappeared.

Testing the hearing by the familiar methods of the watch, the voice, and the tuning-fork, it is found to be unimpaired on the left side; whereas a year ago she could not hear the ticking of a watch beyond eight inches, and could not distinguish low articulate sounds unless the speaker spoke directly into the ear.

But the crowning triumph of the treatment is shown in the condition of the headaches, for she tells me that they now never last more than five minutes; so that I almost think they are now no more than neuralgic twinges, inasmuch as they are never accompanied by either emesis or nausea.

This is an extremely interesting illustration of the chronicity of certain intracranial lesions. Whether the improvement is due to the inherent tendency to recovery or to the curative effects of treatment, who can tell? These cases do certainly seem to improve at times under medicines and special forms of treatment, and occasionally with such promptitude as to render it positive that the medication is to be credited with it. These curative agents are the iodides, mercury (preferably by inunction), cerebral galvanization, and occasional doses of quinine and bromide of potash. The iodides should be given in doses as high as twenty or thirty grains three times daily; the mercury should be rubbed into the armpits or into the soft flexor surfaces of the limbs. In the galvanization of the cerebrum large electrodes, well moistened with hot water, should be used, from three to five milliamperes of electricity being employed. Five grains of sulphate of quinine and thirty grains of bromide of potash should be given at bedtime every two or three weeks.

COMMUNICATIONS.

ANTISEPTIC SURGERY IN COUNTRY PRACTICE.[1]

BY J. M. TAYLOR, M.D.,
CORINTH, MISS.,
EX-PRESIDENT MISSISSIPPI STATE MED. ASSOCIATION AND OF MISSISSIPPI STATE BOARD OF HEALTH, ETC.

In medio tutissimus ibis.

One of the characteristic and distinctive features of this Association, I presume, will be the large element of country practitioners of surgery and gynecology who will constitute its membership. Doubtless a very large proportion of the reports that will be read at the annual meetings will represent the practice done in the comparatively small towns and villages and on the plantations and farms in the Southern States. Very few large hospitals or other eleemosynary institutions will be represented in it. Consequently, those subjects and those methods which more peculiarly interest and pertain to that class of practitioners should be selected for especial consideration in our deliberations. Simplicity of details, and economy both in time and in money, are matters of the very greatest importance to them. Many of them ride by day and by night, on horseback, in buggies, and on railroad trains, in all seasons, over the hills and through the swamps, carrying, in a pair of saddle-bags or a little hand-bag, all the medicines, instruments and appliances used by them in the treatment of all diseases and injuries, medical, surgical and obstetrical. They often visit a considerable number of patients on the same day, requiring diverse treatment, some of them many miles apart. In many instances they have to contend single-handed against poverty, ignorance and filth, separately or combined. Under such circumstances they can afford neither time nor money for non-essentials, either in theory or in practice. They soon become self-reliant, and learn to discard everything superfluous or unnecessary. No class of practitioners is less restrained by the formalities and the prescriptions of authority than they. Being more interested in the utilitarian than the speculative theories of the profession, they are sometimes in advance of their more fortunate (?) city brethren on practical questions, even though they should not be *au fait* in the latest sensation.

[1] Read at the meeting of the Southern Surgical and Gynecological Association, at Birmingham, Ala., Dec., 1888.

If half that has been said and written in behalf of antiseptic surgery were true, it is doubtful whether the country practitioner should feel more grateful for it as a great discovery, or more discouraged by the extravagant and impracticable conditions which it imposes. Although these conditions have been greatly simplified of late, and much of its complexity has been abandoned, still all the details now required are practicable only in hospitals and in the homes of the more wealthy classes. Consequently, if country practitioners should encumber themselves with all the paraphernalia required, the environment of their patients in a large proportion of cases would render it useless. Admitting, then, that the doctrine is true as claimed, the strict rules of antiseptic practice can be followed by country practitioners only in a limited number of cases, as the subject is now understood.

I am not vain enough to undertake a thorough critical review of antiseptic surgery. A subject which has occupied so much space in all our medical journals for so many years must be sufficiently familiar to every physician in the country. And having no new facts to present, it would be a waste of time to reiterate that which is already known to everybody, even if I were competent to do so—which is by no means the case. But a few practical reflections on some of its more salient points may be allowable.

Inasmuch as great latitude has been taken in the consideration of antisepticism which includes all that is meant by antiseptic surgery, it may be well to define what is meant by the term as used in this paper. According to some, it is used to include not only all means used to destroy germs *in esse*, and to prevent their generation, but also to prevent infection from any and every other source. Perhaps but little fault can be found philologically with this definition. But practically it is not correct, and I would restrict it to a consideration of the means and methods proposed for the destruction and prevention of micro-organisms of all kinds, on the assumption that they are the specific causes, the actual, and active, and only pathogenetic agents in the several diseases in which they are found. The use of the term, as applied to means to prevent sepsis from any other source, is an afterthought, is not the construction intended by its originators. The term phrenology would imply, from its etymological construction, mental philosophy, or the science of the

mind in its broadest sense; but we all understand by that term, as it is commonly used, what has been vulgarly called "bumpology," or the art of telling the peculiarities of individuals by palpation of the head, or, if you please, cerebral localization. In a single word, then, I would define antisepticism, as applied to antiseptic surgery by modern writers and practitioners, as *Bacteriopathy*.

As all know, it is founded on the germ theory of disease, one of the most beautiful and plausible theories that was ever launched on the sea of medical philosophy. But it is another striking example of the tendency in our profession to seek for a principle before the facts upon which it is founded have been sufficiently investigated and established. Indeed, the medical profession has been dominated from time to time all through its history by theories which have received more or less general endorsement, some of which, when subjected to the crucial tests of time and experience, have been rejected as false *in toto*, while many of them, though containing many false facts, have developed some important scientific truths, and have contributed some real and useful precepts to the practice.

Cullen said: "There are more false facts than false theories in medicine." But when we take a retrospect of its history from the earliest days to the present time, we find much that is false in theory and in fact. Current medical literature has always abounded in chaff, from which it is often difficult, for the time being, to separate the grain. Leaving out the vagaries of homœopathy, allopathy, hydropathy, Thompsonianism, electicism, *et id genus omne*, we need only refer to the doctrines of the various schools from Pythagoras to the present time, and to the transient systems of practice based on them, which have held sway for a short season. They are too numerous and varied even to enumerate, but everybody can readily recall many examples. Medicine has been cursed in all ages by so-called discoveries, and many of the greatest minds in the profession in every age have been wasted in the vain pursuit and defense of some imaginary discovery. Paracelsus, a noted teacher of medicine in the 16th century, discovered the doctrine of Tartar, which he said was the cause of all diseases of accumulation, obstruction, and concretion. Thompson discovered that all diseases originate from cold, and that heat and heating remedies supply a perfect panacea. Hahnemann, the founder of homœopathy, discovered that all the maladies which afflict mankind, epidemic, sporadic, idiopathic, and symptomatic, spring from three original diseases, viz.: syphilis, sycosis, and the itch. His *similia similibus*, dilute potencies, and infinitesimal doses are therapeutical novelties worthy of his pathology. And now comes along the doctrine of the germ theory, which teaches that all diseases originate from specific germs or living organisms. We have the bacterium of suppuration, the bacillus of tuberculosis, the bacillus of syphilis, of hydrophobia, of cholera, of tetanus, the gonococcus of gonorrhœa, etc.

This beautiful theory supplies a desideratum in etiology long felt, and furnishes an easy solution to many problems which have greatly perplexed the profession for many generations. Immediately after its promulgation, the fertile mind of the discoverer, ever on the alert for something new, was set to work to find some means of killing these microbes, which, like the giants that peopled Don Quixote's brain, cause all the miseries and all the woes that afflict mankind. Antiseptic surgery, Minerva-like, sprang into existence in full panoply, and has carried the medical profession by storm, with all its boasted modern advancements. So strongly is it endorsed, that it is almost as much as any ordinary man's professional scalp is worth to express any doubts of its entire correctness. Carbolic acid long stood at the head of the list of germicides. Not only the hands and instruments of the surgeon, but all dressings, were required to be constantly wet with a solution of it, and the very atmosphere of the operating-room must be filled with its fumes. A complicated apparatus was required to generate the spray, which, however, proved to be so unhandy and so inconvenient that it was found to be unnecessary and has been abandoned by many operators. To say the least of it, it is possible that more lives have been lost by it than by the microbes it was intended to kill.

Without attempting to enumerate all or any of the minor agents recommended and used as germicides, I will only mention the latest, bichloride of mercury. This is all the fashion now, having supplanted carbolic acid to a very great extent. It is a most virulent poison, and to be at all safe it must be diluted to homœopathic proportions. Even then, if strong enough to be relied on as a germicide, it is not devoid of danger. Billroth says: "Corrosive sublimate in dilute solution is practically inert as an antiseptic application to wounds, and

renders the patient and surgeon alike liable to mercurial poisoning. Carbolic acid, known to be dangerous in strong solution, is in very weak ones as good for wound irrigation as clean water, but probably no better."

We are not yet freed from the superstition and credulity which have always prevailed in our profession. We are still liable to be captivated and led astray by the plausible deductions and legitimate conclusions drawn from false premises by enthusiastic discoverers; and if we look with contempt and pity on the absurdities of the exploded doctrines of our predecessors, we doubtless shall meet the same fate from our successors. It yet remains to be proved that the discovery of bacteriopathy is any more true or practically useful than homœopathy or hydropathy. False and absurd as these latter may be in theory and in fact, nobody will deny that they have accomplished good results in practice. And if antisepticism in surgery should accomplish nothing more than to demonstrate the great advantages of absolute cleanliness, it will have accomplished incalculable good. It will not be the first instance in which exhaustive studies and experiments have been made in pursuit of a false theory, whereby grand results, not contemplated and not anticipated, have been accomplished. Astrology, diligently studied for many centuries, for the purpose of learning how to foretell and even to control future events, led to the grand and beautiful results of astronomy; and alchemy, which engaged the minds and the life-time studies of the greatest philosophers of the world, whose object was to find out the secret of converting the baser metals into gold and silver, and to discover the elixir of life or the art of preserving human life indefinitely, resulted in the splendid achievements of modern chemistry. I would not, therefore, underrate the labors and investigations of such men as Pasteur, Koch, Klebs, Cohn, Cohnheim, Virchow, Tyndall, and others in Europe and America, engaged in similar studies. I confidently expect important results from their labors, whether the germ theory be established or not. But any system of practice founded on a theory not yet proved to be true is premature, and is destined to be severely pruned, if not entirely discarded, by the inexorable hand of time. Whatever of truth there may be in it, of course, will stand the tests of time; but the errors will be relegated to the limbo of their predecessors.

The frequent presence of bacteria or other micro-organisms in disease-processes, is generally admitted, and seems to be easily demonstrated. But their functions, or their relations to those processes as cause or effect, are not established and do not seem likely to be soon. Opposed to the theory of their agency as etiological factors, we have the hypothetical doctrine of their incidental or accidental presence as natural scavengers for the consumption of effete matter. The extreme minuteness of these bodies, requiring the most powerful microscopes for their investigation, as well as the great liability to optical illusions, makes it so difficult to understand their true relation to their surroundings, and to define their exact agency in disease, that we should be very slow to found upon their presence any theory, or any system of practice, calculated to revolutionize the established methods of many centuries.

Bacteria or micrococci have been found in great quantities on the mucous membranes, in the blood, and in the fecal discharges of healthy persons. They have been found under Lister's antiseptic dressings without suppuration following. It is asserted furthermore, by high authority, that suppuration can be produced without the presence of minute organisms of any kind. The bacillus of tuberculosis, from the discovery of which we were induced to hope so much, has been found under such varying circumstances, that nothing practical seems likely to result from it. The same may be said of all the rest, except perhaps the bacillus of anthrax, which alone seems to have met all the requirements of mycologists, as a specific and demonstrable cause of disease. In the case of all the others the conclusion is merely from analogy. It is claimed that a septic liquid may retain its poisonous qualities after all microbes have been destroyed in it, and it seems to be proved by experiments that septic poisoning can be produced in animals by the products of organic decomposition without the presence of living organisms. It is claimed that bacteria become most numerous in materials of a septic or infectious character, after the period of their toxic intensity has passed by. Wherefore it may be assumed with equal authority, that all the effects usually attributed to disease germs may be caused by the toxic action of the soil in which they have existed, whether it is membrane, urine, blood, virus, artificial culture material, or anything else.

In this connection the pathogenetic agency of ptomaines and leucomaines should be

duly considered. But I do not propose to consume any time with that subject, although it is now engaging, in its investigation, some of the ablest chemists and biologists in the world. If the researches of Gautier, of Brieger and others engaged in its study, should verify their etiological importance, and if the claims of bacteriologists should be established, our profession will be completely revolutionized, and all our present systems of etiology, pathology, and therapeutics will be supplanted. But however much we may boast of our superior attainments and enlightenment, it is not at all probable that we are so far superior to our ancestors as to warrant any such expectations. It is a fact, I believe, that every generation has considered itself much smarter than its predecessors, but yet we find "that history merely repeats itself."

But I have already extended the limits and scope of this paper beyond what was intended when I commenced writing, and I will conclude with a few practical suggestions for the benefit of my country brethren. It is a fact undenied, and probably undeniable, that the mortality from wounds and surgical operations, especially in hospital practice, has been greatly reduced since the introduction of antisepticism. But it is a significant fact, that the very highest degree of success has been achieved by surgeons who do not use the antiseptic methods. And this is not due to accidental or fortuitous circumstances. Surgeons of equal qualifications have operated at the same time, in the same hospitals, one with and the other without all the rules of antisepticism, with equal success. I venture the assertion, that the qualified general or country practitioner who uses no antiseptics *per se*, can boast a degree of success equal to that of the most distinguished specialist with all the antiseptic appliances most rigidly enforced. I will not consume time in an attempt to enumerate the causes of this, or the causes of the great decrease in mortality, not the least of which is the increased importance attached to cleanliness, and to minute details in operations and in treatment. Ever since the Mosaic laws were promulgated, filth as a factor in disease has been more or less appreciated in all civilized countries. But never has this appreciation taken such practical shape as it has done within the last few years. The fact is established and admitted by everybody; but like many other facts in medicine, it is empirical, its *modus operandi* is not as yet understood. Great harm has been done to the profession by the crude philosophy and hasty conclusions of pseudo-scientists, which constitute the great bulk of our literature on this subject. It matters not how distinguished the writers may be, and it matters not how plausible their reasoning may be; if it is not based on original research, and on premises well established, their conclusions are not reliable. They may be familiar with the microscope, and they may be able to focus micro-organisms, and yet not be reliable. Very few men in the world are qualified to give authoritative opinions on this subject, and such men are about the last to promulgate a dogmatic declaration on this or any other subject. No amount of study and speculation on other men's labors can settle any question until all the basic facts have been clearly evolved and established. I would therefore caution my country brethren, and all general practitioners, who are practical, if anything, to beware of hasty and imperfect conclusions. Wait until all doubts and uncertainties have been removed by those who alone can do it. Avoid the growing spirit of reckless experimentation. In the meantime, let us stick to those means and methods which have given success to our fathers, and which have enabled us to achieve results which we can compare with pride and confidence with the best of them. I would not reject anything because it is new, but I would not adopt it merely because it is plausible.

FRACTURES OF THE FOREARM.[1]

BY JOHN BROWNRIGG, M.D.,
COLUMBUS, MISS.

Believing that we have not attained a perfect method of treating the most common fractures of the forearm, I present for your consideration some new appliances which have been used with good results. In these fractures it is best to prevent flexion, extension, pronation and supination of the forearm. It is also necessary to keep the forearm splints parallel to each other transversely and longitudinally. Collis's and Barton's fractures require a different appliance, which will be described separately.

Fractures Above the Lower Third.

The roller bandage has done so much harm in unskillful hands that I have abandoned its use except on the hand. With the

[1] Read at the meeting of the Southern Surgical and Gynecological Association, at Birmingham, Ala., Dec., 1888.

elbow flexed at a right angle, the inside splint should be a little wider than the forearm, and long enough to extend from behind the elbow to the metacarpo-phalangeal articulation. The outside splint should be of the same width, and long enough to extend from behind the elbow to near the styloid process of the ulna, and should be cut out under the thumb. Two pieces, of the same thickness as the splints and one inch wide, should be shouldered into the outside and inside forearm splints so as to present a plane surface with them, and secured to the splints with little nails, so that these pieces will be at right angles with the splints, and opposite the axis of the arm, and long enough to extend up the arm to below the prominence of the deltoid muscle. To these inch-wide pieces are tacked, next to the arm and above the elbow, two bands of tarboard, wide enough together to envelop the arm and meet above the forearm at the elbow as flexed, and extending upward as high as the inch-wide pieces. If higher, they will be pushed down by the prominence of the deltoid muscle, and the splints with them, so that the bones will be bent at the point of fracture. The pieces of tarboard should be soaked in hot water, so as to be molded to fit the arm, and lined with cotton wadding and cloth next the skin.

The forearm splints should be cut an inch longer than necessary, and, after the tarboard bands are tacked on, apply the splints, and mold the tarboard bands to fit the arm, and then cut the lower end of the splints off, the right length.

The forearm splints should be notched on their outer edges, to keep the strips of cloth to be tied around them from slipping. Strips of cotton wadding should then be laid on the side of the splints next the arm so as to fit the arm, in some places thick, in others thin, and a piece of cloth sewed around the cotton wadding and splints, drawn so tight as to cause the cotton wadding and cloth covering to present a slightly convex surface, as used by the late Dr. F. H. Hamilton on his forearm splints. Too much convexity is not desirable, as the bones may be pushed too far apart, particularly if the strips of cloth are tied too tight around them. There should be but little cotton under the hand and at the elbow.

When the bones are from any cause disposed to separate too far, a many-tailed bandage, applied at the point of separation and extending to the hand, will prevent it. Apply a narrow roller bandage to the hand from the wrist to near the end of the fingers, apply the splints, and, if they fit, bind them on with a few strips of cotton cloth, tied around the arm and forearm parts, so as to exercise gentle pressure. These strips can be loosened or tightened by anyone as the arm swells or shrinks. These convex pads serve well to keep the bones apart, but caution is required in their use, as by binding them too tight the bones may be forced too wide apart or pressed out of position.

When the ulna is broken near its middle, the upper fragment is sometimes drawn away from, and the lower toward, the radius, so as to cause a separation of the broken ends. It is at this point that ununited fracture often occurs. To prevent this, a strip of thin board, not quite so wide as the space between the lower edges of the forearm splints when applied, should be padded with cotton and rolled in cotton cloth and placed underneath the strips which bind the splints on, so as to keep the ulna straight. This thin board should be of the same length as the outside splint. The forearm should then be placed in a sling with thin strips of wood sewed in its upper edges.

In 1885 I read a paper before the Mississippi State Medical Association, describing two rectangular splints, which I had used in these fractures, before I had seen Dr. John H. Packard's account of the use of an internal rectangular splint.

Dr. Scott's rectangular splint prevents motion of the elbow, pronation and supination, but does not provide for keeping the bones apart, and the forearm is in a position of forced supination, which is very uncomfortable. Finding the straight rectangular splints disposed to slip down, I adopted those described above. Very moderate pressure is required, and it is difficult to displace them. A many-tailed bandage should be tied around the hand and splint to keep the hand up.

Barton's or Collis's Fracture.

All the fractures at the lower end of the radius, whether transverse or comminuted, or the oblique fracture first described by Dr. Barton, require extension and counter-extension. These cannot be obtained by using the hand as a lever and the lower end of the ulna as a fulcrum, even when its semi-articulation with the carpus is not destroyed. The displaced fragments cannot be forced into position and kept there by coaptation splints, and if this could be accomplished, the amount of pressure required leaves the wrist and hand stiffened. Fractures near a joint almost always leave the joint stiffened

unless early motion is resorted to. This inflammation is almost certain to attack the articulations of the carpus. Internal and external coaptation splints, no matter how shaped, prevent motion, and more or less pressure on the carpus is necessary. It is important to preserve the proper position of the lower end of the ulna in relation to the carpus. The cause of the loss of prominence of the styloid process of the ulna is due to the twisting of the carpus with the fragment of the radius attached inward, and it is also drawn to the radial side of the forearm by the contraction of the muscles attached to the hand. This displacement of the lower end of the ulna is more marked when its semi-articulation with the carpus is destroyed. The contraction of the muscles causing this displacement should be resisted by extension and counter-extension. If one grasps the hand and twists it forcibly inward a good idea can be formed of the manner in which this displacement occurs. If the muscles of the forearm are resisted by extension and counter-extension in the direction of the axis of the radius, there will be a tendency to readjustment of the fragments, and with very little lateral support this can be accomplished. For this purpose I use a splint composed of an iron bar, sufficiently strong to prevent motion of the elbow, and to keep it flexed at a right angle. The bar extends from below the prominence of the deltoid muscle to the elbow, where it is bent so as not to press on the elbow, thence along the radial side of the forearm, which is between pronation and supination, the thumb being upward; to beyond the end of the first phalanges, the hand being flexed, where it is bent downward at a right angle about three inches. Where the bar passes over the thumb, it is bent upward so as not to press on it. In front of the arm a tarboard splint or band is riveted to the bar, wide enough to extend from the top of the bar to near the forearm, and long enough nearly to envelop the arm.

To the forearm part of this bar is secured a similar tarboard splint, by two strips of sheet iron, riveted to the tarboard splint and bent loosely over the iron bar, so that the splint can be made to slide up or down on the bar. This tarboard splint should be as wide as the forearm on its inside, and a little over half as wide on the outside of the forearm, care being taken that it is not wide enough to press on the styloid process of the ulna nor on the ulna. It should be long enough to extend from near the elbow to the lower end of the radius. The hand should be flexed loosely, the ends of the first, second, and third fingers resting easily on the ball of the thumb. A roller bandage about an inch and a half wide should be passed around the wrist three times and the end stitched. A broad band should be stitched to the bandage around the wrist on the back of the hand, and carried around the flexed fingers and stitched to the bandage on the inside of the hand at the wrist, to retain the fingers in a flexed position. The object of this is to preserve the parallel position of the metacarpal bones, and to prevent their being folded inward upon each other by the extension band, described as follows: A belt cut bias to fit the hand near the carpus, and buckled securely, so as not to slip over the hand, is applied. Two rings of brass or other metal are sewed to the lower edge of this belt, one on the outside and the other on the inside of the hand. Extension is obtained by a cord passed first over the bent lower end of the bar, the ends being then passed through the rings and tied over the bent end of the bar. Counter-extension is obtained by the pressure of the tarboard splint against the arm above the elbow.

The tarboard splints should be lined with cotton wadding and cloth next the skin, and secured to the arm and forearm by many-tailed bandages, the ends being tied together. After the cord is tightened sufficiently, the forearm tarboard splint should be slipped on the bar toward the hand until the lower end reaches near the carpus, and can be made to act as a coaptation splint at the point of fracture, but only gentle pressure is required, the contraction of the forearm muscles causing the displacement being resisted by extension and counter-extension.

Sometimes a narrow roller bandage is required to keep the hand from swelling.

Constant slight motion of the carpus is permitted. When the splint is applied, the thumb should be under the iron bar. This can be secured by applying the belt around the hand so that the ring on the back of the hand will be near the thumb, and the one on the palmar side nearer the little finger. This causes the hand to be twisted outward, which is the reverse of the abnormal position resulting from the fracture.

If greater lateral pressure should be required, it can be obtained by two pieces of thin board placed transversely opposite the point of fracture, one inside and the

other outside the forearm, the ends projecting a little so that cords can be tied around them below and above the forearm. These pieces will press as required on the tarboard splint. I have only had to resort to this in a case of ununited fracture of eight weeks' standing.

THE PREVENTION OF CONCEPTION.

BY H. B. RUNNALLS, M.R.C.S., L.S.A. (ENG.),
BEDFORD, PA.

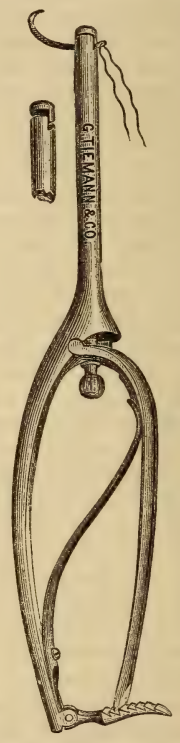
I have read with interest the various papers which have appeared in the REPORTER, upon this subject, and I believe that, if it is discussed upon purely scientific grounds, nothing but good can result from it, both for the public and the profession; but if it is written upon with a view to providing means for preventing conception, from pecuniary or social motives, then, in my opinion, it would be well to allow the matter to drop. Long ago I thought, and I still think, that the law should make it a "criminal act" for members of either sex, suffering from constitutional diseases which might be transmitted to their offspring, to indulge in sexual intercourse; for the effect of such intercourse is usually to reduce the physical standard of a nation, and to produce a population to whom life is a misery. It would be well, perhaps, if the law forbade marriage unless the parties concerned were, first of all, examined by medical experts. That there are cases which come under this notice, in which, after marriage or after the birth of children, means to prevent conception should be adopted, I am prepared to grant; and in these cases, it should only be suggested after the reasons for such had been explained. I would always advise it where puerperal or uræmic convulsions accompanied pregnancy; where vomiting was severe during pregnancy; where any pelvic deformity existed, or any uterine or ovarian growth was present; where excessive hemorrhage accompanied labor; where the perineum or other parts had been lacerated much during labor; where any hernia of the intestines was present; and where any heart, kidney or lung mischief was present—in fact, in all cases in which the medical attendant was of the opinion that evil results would follow conception; but never merely for social or economic reasons.

Wherein lies the difference between prevention of conception and the production of abortion? It does not much matter whether it is the spermatozoid or the fœtus that is destroyed, the fact is the same. For those whose moral sense has reached such a low standard, the charlatan has already provided the "French letter" and other means; but I hope the day will be far distant when our profession recognizes such practice except for physical reasons.

ASEPTIC NEEDLE-FORCEPS.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

The instrument represented by the engraving will hold any kind of needle—round, flat, straight or curved—and hold it firmly. It has both a diagonal and rectangular slot. In these days of antiseptics, all surgical appliances should be as free as possible from any danger of carrying septic material from one case to another; and any instrument



that can not be readily taken apart for the purpose of cleansing is consequently dangerous. This holder was invented with special reference to the avoidance of any such danger. Being practically composed of only four pieces, it can be taken apart instantly by removing the nut, and cleansed and as readily put together again. I find it a very handy instrument, especially in gynecological operations.

SOCIETY REPORTS.

ITALIAN SOCIETY OF INTERNAL MEDICINE.

FIRST CONGRESS, AT ROME, OCT. 20 TO OCT. 24, 1888.

(*Concluded from p.* 688.)

Monday, October 22.

PROF. CARDARELLI, of Naples, read a paper on the

Treatment of Heart Disease,

in which he said that the first symptom which indicates some kind of organic disturbance of the heart muscle is the increase of the intra-cardiac pressure; this increase produces a slowing of the cardiac rhythm by a stimulation of the peripheral filaments of the pneumogastric nerve; the slowing of the cardiac pulsations produces a great accumulation of blood in the organ, and this prolonged diastole must be followed by a more vigorous systole—hypersystole, as it has been called. If the muscular fibres of the heart are in an abnormal condition, if the nervous apparatus is out of order, the heart cannot resist such an increase of pressure, and, consequently, hypertrophy and dilatation of the cardiac muscle take place. The physician must then at this moment do all he can to sustain the nutrition of the cardiac muscle, and prevent any abnormal activity of it. If the heart continues to find a resistance, it will employ all its latent force; but after a while this will be insufficient, and then the symptoms of cardiac asystole make their appearance. To measure the force of the cardiac muscle, Dr. Cardarelli places a tourniquet on both femoral arteries, and records the sphygmographic tracings. If the latent force of the heart is a feeble one, there will be observed, following the compression of the arteries, a great disturbance of the circulation. If the heart is unable to resist the increased vascular pressure, blood-letting must be resorted to. No alarm should be felt at the depression which sometimes follows it. If the heart is found to be only fatigued, the drugs can be used which are stimulants of the cardiac contractions; but it must not be forgotten that the natural stimulant of the heart is stimulus of the intra-cardiac pressure.

As to the nervous affections of the heart, one must find out whether they are due to trouble with the pneumogastric nerve or with the great sympathetic. To know whether the cause of the disease is an excitation or paralysis of the pneumogastric nerve, the modification of the cardiac rhythm as produced by the pressure of the finger on the nerve trunk in the cervical region must be studied. The liver and stomach must also be carefully examined, as they often are the point of origin of the reflex.

PROF. DE GIOVANNI, of Padua, referred to the discussions which have lately taken place in Germany, in regard to the method of Oertel; Dr. de Giovanni does not think himself that all cardiac patients should be condemned to a forced rest; but still he does not think that such patients should be allowed to take the violent exercises recommended by Oertel; these should be allowed only when the heart is sufficiently resistant to stand the pressure. As a test of the resisting power of the heart Dr. de Giovanni employs hypodermic injections of strychnia, which by producing a contraction of the capillaries interferes with the peripheral circulation; if the heart is able to resist this interference of the circulation, physical exercises may be recommended. This resisting power could be measured by giving gradually increasing doses of strychnia; in this manner the amount of physical exercise which the patient could stand could be regulated. He also employs as a test the elastic bandage of both lower extremities; but this test is a very severe one for patients whose cardiac muscle is severely involved.

PROF. RUMMO detailed the treatment of cardiac diseases with medicines. He insists on the necessity of maintaining the activity of the cardiac muscle on a plane with the resistance which the heart has to overcome; he divides the cardiac drugs into three groups: First, Those that act directly on the myocardium, producing an increase in its contraction; they are: Strophanthine and helleborine. Second, Those that act specially on the muscle and cardiac innervation: Upas antiar, digitalis, erythrophleine, rose laurel (Nerium Oleander). Third, Those that act equally on the heart and its innervation: adonidine and convallamarine.

PROF. MURRI, of Bologna, read a paper on

Fever and Antipyretics,

in which he said that as a result of his experiments he had come to regard fever as only a symptom of the disease which produces it, and not as of nervous origin. He has demonstrated this by extirpating the brain in pigeons and then injecting toxic subtances into their body. He found there

was a certain rise of temperature; the same elevation of temperature he obtained when he injected similar substances into the body of animals which had been dead from two to eight hours, by which time the nervous system had lost its activity. He does not think that the nerve centers regulate the loss of animal heat; for he passed a certain amount of warm water into the stomach and intestines of dogs, leaving in place the lungs and skin, which are the great surfaces by which heat is withdrawn from the body; and yet he obtained a persistent rise of temperature.

He is opposed to the use of antipyretic remedies, on the ground that fever is only a symptom of the disease and not a cause of it; moreover, he thinks that by allowing the fever to remain, the development of certain microbes is prevented, and in some cases that they are even destroyed.

Prof. Maragliano, of Genoa, does not think that fever can in any way destroy the pathogenous microbes, for Dr. Gaffky has proved that Fränkel's diplococcus resists a temperature of 107° F., and the typhoid fever bacillus a temperature of 106° to 107° F. He mentions the fact that soldiers who have made a forced march are sometimes found to have a temperature of 106° F.; without having been previously infected they yet present the symptoms of typhoid fever. This proves that an elevation of temperature is by itself sometimes a cause of disease; and he thinks that in infectious diseases the morbid phenomena observed are due to the fever, and hence must be combated by the proper antipyretic remedies.

Prof. Bozzolo, of Turin, does not think that antipyretics should be done away with, although he agrees with Prof. Murri as regards the influence of pathogenous germs in the production of fever.

Dr. Cantani, of Naples, also thinks that the existence of fever can prevent the development of certain microbes, and in the fever he only finds a reaction of the body against the morbid germs and their products. Instead of using the medicinal antipyretics, which act by diminishing the vital reaction, he prefers to employ such agents as aerations, cold baths, and the ordinary hygienic precautions.

Dr. A. Bianchi read a paper on

Tumefaction of the Spleen in Syphilis.

He has observed a very interesting fact, that the spleen increases in size in every case of syphilis, and assumes a pear-shape, the base of it directed downward. He found that this increase of size of the spleen begins with the appearance of the primitive chancre, attaining its maximum in the second stage of the disease. The mercurial treatment produces a diminution in the size of this organ.

Tuesday, October 23.

Prof. Cantani read a paper on the

Etiology and Treatment of Diabetes,

in which he defined diabetes as a general disease having its localization in the chylopoietic organs. The diminution of carbonic acid gas in the organism of the diabetic patient is a result and not a cause of the morbid process; it is consequent upon the diminution of the oxydation of hydrocarbons. The cause of diabetes he attributes to the too great use of farinaceous and sweet substances; in only rare cases does he think the disease is of nervous origin, and then it is only of a transitory character.

Having treated over one thousand diabetic patients, he finds that the best treatment is the complete suppression of the use of meat; if this is not done in a very strict manner, the sugar will rapidly appear again in the urine. He recommends the use of alkaline lactates, albuminous and fatty food, and alkaline waters, but rejects all the different preparations of bread, as well as medicinal treatment. He considers the cure a final one only when the patient can eat any food without any sugar appearing in the urine.

Prof. Cardarelli, of Naples, thinks that diabetes of nervous origin is more frequent than Dr. Cantani supposes; he has observed two cases in which a traumatism produced the presence of sugar in the urine; he has also observed that diabetes often precedes meningitis, especially in children. The treatment followed in cases of nervous diabetes is the absolute avoidance of meat as food, and this with excellent results.

Prof. de Renzi, of Naples, when he was at Genoa, observed that diabetes was extremely rare; he only met with one or two cases of the disease each year in his wards, and yet the inhabitants of Genoa are great meat eaters. While in Naples, where he now practises, the inhabitants almost altogether live on farinaceous and vegetable substances, and he meets every year in his wards with about forty to fifty diabetic patients. He also thinks that diabetes can have a nervous origin; sudden fright may

produce it. The treatment does not consist in the absolute exclusion of meat; but he allows his patients a certain quantity of it, combined with green vegetables and some wine. Prof. Maragliano does not pay great attention to the quantity of sugar contained in the urine; he watches his patient in regard to his weight; if a rapid decrease in weight occurs, he tries to sustain the patient's general nutrition as much as possible, and gives him a mixed diet, not excluding meat absolutely. He also adds milk and the preparations of strychnia.

Prof. Rummo thinks that some of the cases of diabetes which have been attributed to a nervous origin are due to the fact that primary disease had involved the nervous system early, and that the patient at the time of examination presented nervous symptoms, which made the physician think he had to deal with a case of nervous diabetes.

Prof. Baccelli, of Rome, says that in 1863 he presented the case of a young man who suffered from cerebral concussion after a fall, and died diabetic several years after; and at the post-mortem a cicatrix was found at the centre of the pons Varolii; in this case the nervous origin is unquestionable. In the puerperal states and in pregnancy, glycosuria of nervous origin is often observed.

Prof. Baccelli, of Rome, read a paper on the

Treatment of Hydatid Cyst,

in which he stated that he uses the following method: great antiseptic precautions being taken, about two and one-half drachms of liquid are taken out of the cyst with the hypodermic syringe, and an equal quantity of a solution containing from one-fifth to one grain of corrosive sublimate is injected in its place. The results have been most satisfactory; cure is obtained in about five days, during which time a slight febrile reaction is observed, but the liver returns to its normal form in about that time.

Wednesday, October 24.

Prof. Marchiafava, of Rome, read a paper on the

Plasmodium of Malaria.

He mentions the fact that during the former years only black pigment was observed in the blood of malarial patients, either free or included between the cellular elements; and it was thought to be a residue of the destruction of the coloring matter of the red blood corpuscles. He recalls the fact that for the first time in 1878, he discovered the change of hemoglobine into melanine in the interior of the red blood corpuscles, but never was able to explain this transformation. After the studies made in Algeria by Laveran, and afterward at the Anatomico-Pathological Institute of Rome, he thinks the following conclusion in regard to the destruction of the red blood corpuscles in malarial infection may be reached:

Certain microörganisms penetrate, under one form or another unknown to us, into the system by the inspired air, and from the lungs into the blood; in this last medium, these parasites invade especially the red blood corpuscles, and are found in the early stages as a protoplasmic form endowed with very active amœboid movements; they increase in size within the red blood corpuscle, and live at the expense of its coloring matter, changing this last into pigmentary deposits. These amœboid forms multiply by fission, and then invade new blood corpuscles, and this process continues.

The malarial parasite (*plasmodium malariæ*) is always in the early stages intraglobular, but later it presents itself under different forms. This plasmodium is the type of the intra-cellular parasite, and yet, although not a bacterium, it will produce a general infectious disease. In a doubtful case of malaria, the examination of the blood of the patient will settle the diagnosis. The malarial parasite lives altogether in the blood, and develops, multiplies, and dies in the red blood corpuscle. This parasite might die spontaneously, when a disappearance of the disease is observed; or, again, quinine may have a very marked effect in causing its destruction; but in any way the organism does not come out of the blood, unless taken out by blood-letting. This fact explains the non-contagious character of the disease; should blood of a malarial patient be injected into another man's blood-vessels a case of malaria would certainly be observed.

Dr. Mosso, of Turin, thinks that additional experiments are necessary to sustain the views expressed by Dr. Marchiafava. During his own researches, he has observed, while studying the blood corpuscles under invasion of the so-called parasite, that the protoplasm first becomes transparent, and afterward separates itself from the blood corpuscle. The same fact had been observed by Gaule some years ago, when, by acting on the frog's red blood corpuscles with a

solution of chloride of sodium, he observed that something came out of this corpuscle, and he thought he had to deal with a parasite, whereas, on the contrary, it was only a mass of protoplasm. The same changes Dr. Mosso himself has observed in the blood taken out of the human body; hence, he thinks that Dr. Marchiafava's plasmodium will be proved to exist only if he can prove that these forms are not the result of a degeneration of the cells, following their death; this so-called parasite must also be demonstrated as really penetrating into the red blood corpuscles.

Dr. Maragliano has also observed the changes described by Dr. Mosso as taking place in the red blood corpuscle; but he thinks they can be differentiated from the parasite by the fact that parasites have more regular contours.

Prof. Ferrati, of Catania, read a paper on

Puncture of the Spleen

for chronic tumors of this organ, of malarial origin. He has employed puncture of the spleen in many cases, with excellent results; in a person whose spleen measured sixteen inches in length and eight and two-tenths inches in breadth, the introduction of the needle three times produced a decrease of the tumor, of three fingers' breadth in length, and two in the transverse diameter. The experimenter was led to this method by a desire to know whether or not in the parenchymatous injections of certain liquids the introduction of the needle itself is the real cause of the amelioration.

Prof. Fazio, of Naples, read a paper on

Parenchymatous Injections of Quinine in Chronic Tumors of the Spleen.

He thinks these intraparenchymatous injections of quinine are more useful than puncture alone, as they combine both treatments.

Prof. Baccelli read a paper on the

Treatment of Neuralgia by the Hypodermic Injections of Carbolic Acid.

He injects a solution of one per cent. of carbolic acid into the painful part; he has obtained very good results, especially in cases of supraorbital, intercostal, and ischiatic neuralgias, and also in the articular pains of chronic rheumatism. This same treatment he has used in a case of tetanus, injecting the substance every hour; he used at first one-fifth grain of carbolic acid for each injection, then two-fifths grain. The spasms disappeared gradually, and the patient was well in eight days.

Dr. Sonsino, of Pisa, read a paper on the

Treatment of Ankylostomasia with Thymol,

in which he said he had to treat, some time ago, a young woman about 18 years old; she was anemic, had amenorrhœa, was not well developed for her age; she said that while in the country she drank water from a certain river. Iron was given her without success; examining the fæces finally by the aid of the microscope, he found he had to deal with a case of ankylostomasia; thymol was given her in repeated doses of sixty grains, and she evacuated about one hundred and thirty of the parasites. A few days later, the renewal of the treatment produced the evacuation of seventy more. The patient took twenty-three grammes (six drachms) of thymol in all. He recommends, in cases of intractable chlorosis, to search for the eggs of ankylostomata.

Before separating, the Congress selected Rome as the permanent place of reunion. The next meeting of the Congress is to be held in 1890; Prof. Baccelli, of Rome, will be President.

Reports of Clinics.

College of Physicians and Surgeons—Vanderbilt Clinic.

Medical Clinic—Prof. Delafield.

Pleurisy with Effusion.

The patient was a man, 26 years old, who has been sick two weeks, his illness beginning with a "stitch" in the right side low down in the axillary line. The pain continued, and was felt also in the front of the chest. Dyspnœa was also complained of.

He was well in every other respect—no headache, no vomiting, bowels regular, and appetite good. His temperature, when he first presented himself at the Clinic some days ago, was 101°; to-day it is 99.8°.

Examination shows the patient to be somewhat emaciated; his chest has the characteristic shape seen in emphysema of the lungs, that is, a bulging of the costal cartilages on each side of the sternum. The percussion note over the upper part of the chest in front has a different quality from that of the normal pulmonary resonance. The respiratory murmur is less distinct on the right side than it should be; on the left side it is good. The apex of the heart is in

normal position, and there is no murmur. Posteriorly the left side shows nothing abnormal. On the right side there is dulness from the middle of the scapula to its angle, and below this there is flatness. The breathing and the voice are heard to the line of the flatness. This, then, is a straightforward case of pleurisy with effusion. It illustrates well the slight effect this disease may have upon a patient. The man suffers now only from slight pain and some shortness of breath, and says he feels well able to go to work. It is easy to see how practitioners can overlook such a case; the symptoms being so slight they neglect to make a physical examination of the chest.

When this man first came under treatment the fluid reached to the middle of the scapula; now its limit is marked by the line of flatness and loss of respiratory murmur and voice on auscultation. This is a very good result, and it has been obtained by rest, the application of iodine to the chest, and the administration of a simple cough-mixture—really no treatment.

And yet rest is the most important element in the cure of these cases. Allow this patient to go to work, to expose himself to changes in the weather, etc., and in a few days his chest would be found half-full of fluid. But keep him at rest until the fluid has all disappeared and the patient has felt himself well for some little while, and a permanent cure will be obtained in the shortest time.

Dilatation of Stomach (?)

This patient was a man, 23 years old, a shoemaker by occupation. His work is not heavy; he has very little stooping to do; he does not press anything against his chest while at work. He has been sick one year, and complains of dull pain in the right side just below the free border of the ribs. It comes and goes. He has never felt it at night. At first it would appear only occasionally, and he might go two or three days without it; but latterly it has been growing worse, so that he has it now almost every day. In some weeks he has a respite, but in others the pain remains all the time. The patient does not complain in any other way; his appetite is good, his bowels regular, and he attends to his work. The urine shows a specific gravity of 1022; it is alkaline in reaction and does not contain albumin. Examination reveals nothing abnormal about either lungs or heart. The liver is normal in size and position. There is a fullness noted in the epigastric region, and on kneading this a distinct splashing sound is heard. But this man says he has eaten his lunch only two hours ago, and the knowledge of his coming here may have produced sufficient excitement to retard digestion. His stomach at present is full and dilated. But is this a pathological or a physiological dilatation? It is very common, at the present time, to make a diagnosis of dilatation of the stomach on imperfect data. To be pathological the dilatation must exist during the greater part of the time. In the present instance, having never seen this patient before, it would be impossible to make a positive diagnosis. If his stomach were at all times as large as it is now, it would certainly be dilated. In this patient there is simply a history of pain; and the character of the pain is such as to incline one to exclude organic disease. On examination we are able to add only two facts to this history, namely, the dilatation of the stomach and the alkalinity of the urine. This man has not been taking medicine to produce such an effect, and in a young man we do not expect to find alkaline urine. These three facts, therefore, point to *some* disturbance of digestion. The character of the pains—wherever they may be situated—are quite pathognomic of such a state; but our history does not cover a period long enough to make a positive diagnosis.

We shall instruct this patient to return next Thursday. During the week he will be allowed only one solid meal a day, and that to consist of meat and potatoes alone. For the rest, he may drink milk. He shall come to us without having previously eaten for three hours. We will then test his stomach contents, which will be removed with the stomach pump.

Chronic Endarteritis.

This patient was also a man; he was 65 years old, a native of Ireland, and a laborer by occupation. He has suffered for the past twelve years with attacks of unconsciousness, which come on suddenly so that he usually falls to the ground without having any premonition of their appearance. They last usually about fifteen minutes, and leave him without palsy or other sign except headache, so that he can return to work in one hour after the attack.

Sometimes the attacks are more severe. They have increased in severity as well as in frequency lately, so that he has had four during the last five weeks; two attacks occurred on last Wednesday. The patient has not worked for the past six months, though

he is able to work. He complains quite constantly of "tightness of head" and failing memory—though he is able to apply his mind; and also of very poor appetite; his bowels are somewhat constipated. There is no sleepiness during the day, and he sleeps well at night; there is no vomiting. On only one occasion were there noticed twitchings of the right side of the face; he has never had any other convulsive movements.

His urine has a sp. gr. of 1004, and contains no albumin. Examination shows the tension of the radial arteries to be decidedly increased; they are not large and not tortuous. The lungs show evidence of emphysema. The heart's action is feeble in proportion to the arterial tension. It is not rapid, and is regular; there is no murmur.

This patient represents a class of cases which is difficult and even uncertain of diagnosis. We are usually satisfied with a probable diagnosis. The man does not look ill, though he has been sick twelve years.

What is the matter with him? [The students suggested many diagnoses; tumor of the brain and chronic pachymeningitis—both of which Dr. Delafield remarked were possible; chronic Bright's disease—which he had no doubt the patient suffered from, but which would not account for his attacks; cerebral anæmia and cerebral congestion—which he styled loose talking; and chronic endarteritis of the cerebral arteries. The last was the correct diagnosis.]

Continuing his remarks, Dr. Delafield said: These cases are not so very uncommon. But how can the fact be explained that the man has been sick so long and looks so well, and yet is suffering from endarteritis? We suppose the same happens here as so often happens in cases of cancer of the stomach. How frequently such a patient is heard to declare that he has been complaining of his stomach symptoms for five years, whereas his cancer has existed but two years, and previous to this time he suffered from dyspepsia.

This man's urine, pulse, and heart-action point to endarteritis; but he has not had it for twelve years.

His first attacks were, in all probability, simply vertigo—of bad form to be sure, but such as are frequently associated with derangements of liver and stomach. Later on, the attacks became associated with true unconsciousness. The patient himself does not note this change in the character of his attacks; he simply sees their increase in severity.

Foreign Correspondence.

JOTTINGS FROM AROUND THE WORLD.

The Melbourne Hospital.—"Consultation Day."—Haphazard Teaching.—Rules Governing Hospital Pupils.—How Nurses are Encouraged.—A Clinical Lecture.

Melbourne, Oct. 1, 1888.

Since my last letter I have made a visit to the Melbourne Hospital. The medical superintendent, Dr. Lewellin, received me most kindly and made my visit interesting and profitable. The exterior of the building is not of an inviting appearance, and the wards within are decidedly old-fashioned. The hospital was founded in 1845; no conception of the future of Melbourne was then held in mind, so that the plan of building and the space allowed were not the same as if the founders could have seen clearly forty years ahead. The result has been constant additions and changes, so that the total effect is not altogether artistic. The medical staff consists of eighteen physicians and surgeons. Here again, as in the case of the Children's Hospital which I reported in my last letter, a committee acts upon the proper cases for charity; in fact, in 1864 an enactment passed the Victorian Parliament making it compulsory for each incorporated institution to be governed by a committee of not less than seven members, to be elected by the contributors. Even in emergency cases the committee allows to those who are able to pay only the most temporary assistance. My first visit was on Tuesday, which proved to be the regular consultation day, as it is called. On this day all new cases for operation are consulted on, a plan of procedure marked out, and the day of operation settled; the result of the consultation is entered in the consultation book, and the medical officers present attach their signatures to the statement. No important operation is performed without a consultation of this kind, and all such operations are performed only on Mondays and Thursdays, at 2.30 P.M. No operation is permitted on Sunday. This hospital is the chief source of clinical teaching for the University students, and on a closer examination of the clinical teaching here, I can but repeat what has already been said on this subject—that clinical teaching is very far inferior to our own in America. There is much haphazard teaching; there seems to be no system; to me it seemed to be in chaos. The remark was overheard: "What are you going to lecture

upon to-morrow, Doctor?" "Oh! let me see," was the answer; "do I lecture to-morrow? Oh, well, I will scare up something from the wards in the morning when I come, and I will give them something or the other." Passing into one of the wards I found bedside instruction going on; about thirty boys were collected about one bed; it was impossible for the most of them to see or even to hear. Poor hungry boys! The pathologist of the hospital is Prof. Allen of the University, of whom I spoke lately. In this particular the University is well served, as Prof. Allen has now the right to take all his specimens to the University, and to use them in class demonstration.

The rules governing the hospital pupils are of interest: after denying them free run of the wards without an officer of the institution, and assigning the exact hours at which they may be in the wards at all, a further useful rule is that they must not enter any ward on the same day on which they may have been in the dead-house, or present at a post-mortem examination, whether at the hospital or elsewhere; this is doubly insisted upon as regards entry into a surgical ward. At the commencement of each term of attendance a pupil must put himself under the charge of some physician or surgeon, and continue with him during the whole of that term. Before the commencement of every term of attendance, each pupil must pay to the Secretary of the Hospital the following sums, in addition to the fees charged by the University for attendance on clinical lectures: (1) For the use of the hospital, twenty-five dollars; (2) for the pathologist, six months, eleven dollars; (3) for use of the dispenser, sixteen dollars, each three months; (4) for the physician or surgeon whose practice the pupil attends, twenty-five dollars. Every hospital physician and every surgeon has two clerks or dressers, who are appointed from the medical students of the University by the medical superintendent, subject to the approval of the committee. These clerks are appointed for six months. I found the nurses here also well drilled, and of a superior character. The reason is evident: after two years' faithful service they have an increase in salary of twenty-five dollars per annum, and a further increase of five dollars per annum for each succeeding year of service, until the sum amounts to sixty-five dollars in excess of the original salary.

In the out-door department the one shilling fee for attendance is adhered to; this is the rule in all the charities in this city. Since the adoption of this rule, Dr. Lewellin says the service has been reduced greatly, which even now is too large, amounting on an average to sixty or seventy a day. Four separate funds are maintained, called respectively the maintenance, the building, the endowment, and the convalescent fund. The latter is interesting, being devoted to five objects, viz.: to defraying the expenses of patients going to the sea-side or to the country; to the purchase of clothing; to defraying the expenses of removing the patients to their homes; to supplying small sums of money to patients leaving, to assist in maintaining them until they are able to return to work; and to providing, partly at least, for the purchase of trusses and other instruments or appliances.

The hospital building is situated in the very heart of the city. Hearing that one of the clinical lectures was to be held the next day, at the appointed time I went and found Mr. Ryan in the arena. He is a genial man of about 40 years of age, and gave a clear lecture on cancer of the tongue, the text being supplied by a young woman who was thus affected. While the girl walked around, and a few general remarks were being passed concerning her, I took the opportunity to take in my surroundings. The amphitheatre was very small, three rows of seats for the students, of whom I counted just thirty-five present. The lecture must be compulsory, as the roll was called. This one case was all that was brought in. The opinion was given that the cancer of the tongue was the result of irritation of some rough teeth; the case had been seen some time before, when there was a true pre-cancerous ulceration, and the girl was then urged to have the teeth attended to, but after neglect she had come back in the condition mentioned. The lecturer insisted that very many cases of cancer of the tongue have their origin in some local irritation, such as teeth, or the improper use of caustics, etc. If there is need of caustics about the tongue, he would use a good one at once—the actual cautery or pernitrate of mercury. He thinks heredity plays very little part in the production of this kind of cancer. In his experience he has found secondary deposits in the internal organs very rare in this variety; why, he is not fully prepared to say. The essence of the lecture was that cancer of the tongue often comes from most trivial causes, and that all irritations and ulcerations in those above twenty-five years of life should be treated promptly and with the least meddling possible; and if operation is

deemed necessary, it should be done at an early date. He related how a mistake was made in that very arena by one of the best surgeons in the city, in diagnosticating cancer of the tongue when, by mere accident as the patient lay on the table ready for operation, it was discovered that the body was full of fresh syphilitic eruptions. On investigation it was shown that the young woman was a prostitute who used her tongue and mouth in sexual intercourse. The chief objection to the lecture is, it was rather too theoretical; the students have a surfeit of that already; it would have given a zest to the hour if more of the same or similar cases had been shown; or, if the hospital had no more cases of cancer of the tongue, to have grouped some of the cancers then in the building, for there were some, as I saw them in the wards after the lecture. To my mind, almost every step of a true clinical lecture should be illustrated from life, the differential diagnosis enforced by cases to the point, the prognosis shown by more advanced cases of the disease, or the same case presented to the class from time to time. Too often a lecture of this kind seems to bear the stamp of "anything to kill time." Especially in Melbourne, where the clinical teaching is meagre, the very best advantage should be taken of all that would carry any lessons to the students.

C. C. VANDERBECK.

LETTER FROM BERLIN.

Prof. Naunyn's Clinical Observations.—Relation of Fränkel's Pneumococcus to the Streptococcus pyogenes.—Persistence of the Spirochetæ of Obermeyer in Recurrent Fever for 14 days.—Multiple Arsenical Neuritis.—Paralysis from Injections of Ether.—Cause of Diabetic Coma.—Fermentations in the Stomach.—Therapeutics of Syphilis.—Curability of Cancer.—Creolin a Substitute for Creasote.

BERLIN, Nov. 9, 1888.

Professor Naunyn, the eminent clinician of Königsberg, who has just accepted a call to Strassburg, has published, as a sort of farewell present to his old northern University, a highly valuable collection of clinical observations. Your correspondent must content himself with alluding only to the most interesting parts of that publication. Prof. Naunyn has observed five cases of lobular pneumonia complicated with empyema, in which both Fränkel's pneumococcus and the streptococcus pyogenes were constantly found. These two microbes hold a certain relation to each other, inasmuch as one pathogenic germ prepares a favorable nidus for the other. Thus, the pus-germs easily develop and predominate in the lungs after the prior invasion of the pneumococcus. Naunyn also relates a case of recurrent fever, in which the spirochetæ of Obermeyer were observed for fourteen days in succession. Formerly it was always thought that these germs appeared in the blood only with the fever and disappeared after a critical fall of temperature. Of considerable interest are Naunyn's observations on paralysis as a symptom of acute arsenical poisoning. In chronic poisoning with arsenic, paralysis is not an unusual symptom, and in the acute toxic paralysis it is at times the only symptom apparent. This paralysis appears quite early, shortly after or in the course of the gastro-intestinal symptoms, and is an expression of a multiple nerve-affection rather than, as has been hitherto thought, of a spinal paralysis.

Of equal interest are Naunyn's observations on paralysis caused by subcutaneous injection of ether. Only a few cases of this ether paralysis have been described. In one case observed by him the paralysis was confined to the region of the ramus profundus radialis (posterior interosseous), while in another case the paralysis was sensory and affected the posterior cutaneous branch of the radial nerve, and lasted for three months. Naunyn believes that the action of an injection of ether (or oil of camphor) does not consist in any specific influence exerted by the ether on the central nervous system, but in a violent irritation of the peripheral sensory nerves directly affected. Another interesting statement made by Naunyn is that coma in diabetic patients is caused by oxybutyric acid circulating in the blood. This acid causes coma by depriving the blood of its alkaline constituents. Experimentally the author has also succeeded in checking the diabetic intoxication by supplying alkalies to the blood. It is therefore a fair inference that alkaline remedies are indicated in diabetic coma.

A larger essay of considerable practical importance is the one on fermentations in the stomach, from which we gather that the normal gastric contents, during the process of digestion, are almost free from germ-life, with the exception of some yeast-cells or some single bacteria. The filtrate of such gastric contents as contain free hydrochloric acid and pepsin may be kept for weeks in

an open vessel without any germ-life being observed. Indeed, the fluid can be inoculated with various microörganisms with impunity. This singular resistance to germ-life is to be attributed, first, to the free hydrochloric acid; for, if the gastric contents are neutralized with an alkali, germ-life develops quickly and abundantly. Pepsin appears also to have something to do with this resistance to microbes, for germs appear at once if the fluid is heated to the boiling-point and after being cooled inoculated with germs. This procedure of course destroys the pepsin. Bacteria cannot normally develop in the gastric juice, as they cannot escape the digestive action of pepsin. Naunyn mentions, as predisposing causes of gastric fermentations: 1. Mechanical insufficiency of the stomach, with secondary insufficiency of secretion, such as may occur in stenosis of the pylorus resulting from carcinoma, ulcer, or muscular weakness of the stomach. 2. Grave organic lesion of the gastric walls, with secondary insufficiency of secretion as occurs in broad carcinomata, and in atrophy of the mucous membrane. 3. Undue supply of neutralizing ingesta. As results of gastric fermentations Naunyn mentions: 1. Irritation of the mucous membrane; 2. Tympanites; 3. Auto-intoxication, such as dyspeptic coma; 4. Interference with normal mechanical procedures, such as peptonization and saccharization; 5. Disturbance of the intestinal functions by the entrance of irritating gastric contents into the intestines. As therapeutic measures Naunyn recommends in gastric fermentations: washing out of the stomach; antiseptic remedies, such as hydrochloric acid, or carbolic acid (three drops before meals); benzol, fifteen to twenty drops; or creasote (six drops). The diet should also be regulated, and a meat diet given in obstinate yeast-fermentation.

Naunyn is an authority on the therapeutics of syphilis. His latest suggestions in the treatment of syphilitic affections of the nervous system are very simple. He recommends, above all, an energetic inunction-treatment, *i. e.*, thirty to forty inunctions containing at least sixty or seventy-five grains of mercurial ointment. He has used as much as two and a half drachms for one inunction. The inunction is to last for fifteen or thirty minutes. Among other therapeutic measures, he advises careful attention to the mouth and skin, regulation of the bowels, selected and nourishing food, and exercise in fresh air. He orders iodide of potash from the beginning in doses of fifteen to forty-five grains a day. The duration of the entire treatment covers usually from eight to ten weeks. In diffuse nephritis and hepatitis mercury is to be used with caution, as it is ill borne.

The case of the Emperor Frederick has naturally again directed the attention of the profession to the medical treatment of cancer. Neudörfer has just published an interesting little pamphlet on the subject. Carcinosis, the author says, is very probably just as curable as syphilis or phthisis. The excision of a carcinoma, as of a hard chancre, is, as a rule, not far-reaching enough to prevent the infiltration of the surrounding tissues with the specific microbes and cells. He believes that the medicinal treatment of cancer should be tried more extensively than has been the case hitherto. The rind of condurango and Chian turpentine have often given promising results. There are also, as in phthisis, climates favorable for cure. On the plateau of Mexico and at the Cape of Good Hope, for instance, cancer is an exceptional disease. The principal office for the surgeon, in Neudörfer's opinion, is not the extirpation of the neoplasm, but the medicinal treatment of the cancer-cachexia, which is the chief factor in bringing about the death. The treatment of cancer is naturally much like that of phthisis. Creasote, which has been found to stimulate the nutrition of the blood-corpuscles, is of equal value in cancer and in phthisis. He has obtained decided results in the treatment of cancer with the following preparation:

℞ Creasoti puri,
Sodii bicarb.,
Olei morrhuæ . . . . . āā f ʒ v
M. Put in 100 gelatine capsules. Take three capsules three times daily after each meal.

A very eligible substitute for creasote is creolin, as it is not only cheaper than the latter, but is also a stimulant of digestion. He prescribes:

℞ Creolin . . . . . ♏ xv
Ext. glycyrrhizæ, q. s. ut ft. pil. No. 100.
Sig. Three pills three times daily.

Locally, Dr. Neudörfer prescribes, with the above pills:

℞ Creolin,
Ichthyol,
Iodide of potash . . . . āā gr. xi
Vaselin,
Lanolin . . . . . āā gr. xv
M. F. ung. Sig. Rub into the part three times daily.

Neudörfer boasts of three actual "cures" of cancer obtained with this treatment.

PERISCOPE.

Influence of the Menstrual Periods Upon the Sex of Children.

At the meeting of the Biological Society of Paris, October 13, 1888 (*Bulletin Médical*, Oct. 17, 1888), M. Dupuy stated that from the study of the statistics of more than two hundred families (over one thousand children) he had found that, the sex of the first child being known, it was possible to predict what would be the sex of the children yet to be born, and in some measure to choose the sex. He then went on to say: The first child being conceived in a menstrual period which we will designate by 1, if the child is a boy, all the children which will be conceived, for example, in the 11th, 13th, 15th, 105th, 107th, 109th, etc., menstrual periods following, will also be boys. All the children which will be conceived in an equal menstrual period, that is to say, in the 12th, 14th, 16th, 106th, 108th, 110th, after the first conception, will be girls.

So, says M. Dupuy, if the father of a family desires to have a girl, after having had a boy, he should count the number of menstrual periods passed by his wife since her last confinement, and bring about pregnancy in an equal menstrual period after the first confinement. If the first child, however, was a girl, then pregnancy should be secured in an odd period. All the children born in a twin pregnancy with a single placenta follow the rule.

He adds that this rule is true only for the children of the same couple. If one of the two parents changes, the count must be made afresh from the first confinement. M. Dupuy declares his ignorance of any cause for this regularity. He has established its existence empirically.

Terebene.

Dr. D. M. Cammann, in a paper upon observations on the use of terebene, gives the following summary of his results: Thirteen cases were of chronic bronchitis, most with more or less extensive pleuritic adhesions. Three were of acute bronchitis, ten of emphysema, two of asthma and bronchitis, ten of phthisis, one of pleurisy, and one of the third stage of pleuro-pneumonia. Two of these, both cases of acute bronchitis, were cured, one in four and the other in eleven days. Thirty-three cases were improved, most of them markedly, but a few only to a slight degree. Five were unimproved, two of the patients being obliged to discontinue the drug after two or three days, as it produced vomiting. The shortest time the treatment was continued in any case was four days, the longest time six months. The average length of treatment was a little over twenty-six days. Most of the patients took fifteen minims and some as much as half a drachm in a mucilaginous mixture four times daily. In all except three, the cough was improved, becoming softer and less frequent. In twenty-six, the quantity of the expectoration was lessened; in four it was unchanged, and in two it was increased. The latter were under treatment only one week, and it was found in some of the other cases that the expectoration was increased for the first few days and afterward diminished. In seventeen cases the expectoration became thinner and more watery; in six it was no thinner. In the other cases no note was kept in regard to this point. In those troubled with dyspnœa, the dyspnœa was diminished in thirteen and undiminished in eight. The patients noticed an increase in the urine in nine cases; no increase was noticed in fifteen. In many of the cases the appetite improved. In two cases the terebene caused vomiting, in two nausea, in one dizziness and nausea, and in two dizziness. These symptoms usually disappeared when the dose was reduced. It is beneficial in affections of the bronchial mucous membrane, both acute and chronic. It relieves the dyspnœa of emphysema, it is readily borne by the stomach, and it seems to have a resolvent action on pleuritic adhesions.—*N. Y. Med. Journal*, Nov. 10, 1888.

—The Trustees of the University of Pennsylvania have accepted the resignations of Prof. D. Hayes Agnew, from the Chair of Surgery, and of Prof. William Osler, from the Chair of Clinical Medicine. Both resignations are to take effect at the close of the present session, in 1889. Dr. John Ashhurst, Jr., has been nominated for the position to be vacated by Dr. Agnew.

—Dr. C. B. Shute and some Malden officials, says the *Ledger*, Nov. 28, went to Worcester some weeks ago to see a new patent ventilator in a hospital. Dr. Shute and Alderman Clark descended a shaft into which was blown the foul air from the building, in which were several typhoid fever cases. Dr. Shute died of the disease and Alderman Clark is down with what is regarded as a fatal attack of it.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

APPARENT DEATH IN THE NEW-BORN INFANT.

Everyone, with even a moderate obstetric practice, meets occasionally with cases of apparent death in the new-born infant. The subject is of interest not only from its exceedingly practical nature, but from the fact that neither the pathology nor the treatment of the conditions presented is absolutely settled. Further investigations are needed to determine whether the states of lividity from congestion, and pallor from anæmia of the superficies, are etiologically the same, and but different stages of the same process; or are as different in their etiology and real nature, as in their external appearance. No matter which view is correct, the usual division is important in both prognosis and treatment.

For the less serious cases, in which, although cyanosis is present, respiration is feebly and imperfectly performed, nothing succeeds better than the simple expedient of irritating the skin along the spine by somewhat vigorous friction with the fingers. Respiration and vigorous crying are soon established. In this particular class of cases nothing has given so much satisfaction as this manœuvre. When cyanosis is more marked, and especially if there is reason to think from a history of prolonged second stage that attempts at respiration have been made before birth, with aspiration of fluid into the air-passages, the mouth and throat should be cleared of mucus, etc., by a cloth introduced on the finger. The usual practice, under these circumstances, of immediately cutting the cord and allowing one or two drachms of blood to escape, before applying the ligature, probably relieves the heart and is to be commended; but much time should not be thus consumed. A hot bath favors bleeding and at the same time stimulates respiration. Cold water or brandy may also be sprinkled from a height at intervals to cause inspiration; but it seems to us that the plan of dipping a new-born infant into cold water should be used only under exceptional circumstances. Inversion of the infant is a logical and valuable method of treatment in all stages of asphyxia, and should be resorted to early. The other measures of treatment can be, at least in part, applied with the infant inverted. The judicious use of these measures will bring about respiration in the vast majority of cases of asphyxia livida. In some cases artificial respiration will be necessary. Sylvester's method can easily be used with the infant in an inverted position. Each of the other methods of producing artificial respiration has certain advantages. Schultze's method has few adherents in this country. Its apparent brutality will hardly permit it to be popular with the laity.

The methods of Byrd and Goodell are similar in principle and execution, and, owing to the gentleness of the manipulations employed, are especially applicable to feeble infants.

The prognosis is much more grave in asphyxia pallida; great feebleness in the action of the heart is added to the absence of respiration. Cutaneous stimulation by means of the hot bath, with intermittent sprinkling with cold water is not likely to succeed. Flagellation, which is permissible and useful in the livid form, is contra-indicated, lest the feebly acting heart should cease to beat. The cord should be quickly cut, the upper air-passages cleared of mucus, and artificial respiration resorted to, care being taken that the head is kept lower than the body. We prefer the method of Sylvester or Goodell, because of the less amount of exposure that is necessary, and less amount of shock that is inflicted. Jacobi has made the valuable recommendation that an enema of water at a temperature of 104° to 108° Fahr. be given. Perhaps a few drops of brandy could be added with advantage. Faradization of the phrenic nerve is a promising expedient, and of even greater promise in the livid form. One pole should be applied over the sterno-mastoid muscle, the other over the diaphragm. One electrode should be kept stationary, the other applied intermittently to bring about inspiration. Unfortunately a battery is not always at hand. Direct insufflation is at times resorted to, but has serious disadvantages. Where all secretions have not been removed from the throat, this foreign material is liable to be driven into the trachea and bronchi. The method of insufflation through a catheter, unless used with great care, is liable to cause rupture of the pulmonary air-vesicles and interlobular emphysema, as we have seen in one case. When mouth-to-mouth insufflation is used the stomach is likely to become inflated and still further embarrass respiration. Owing to the inherent dangers of the method, direct inflation should not be employed until more simple measures have failed. As a *dernier ressort*, in some cases, tracheotomy has been done and the catheter introduced directly into the trachea. Nor should it be forgotten that too much may be done, especially in feeble infants. Many cases are on record, similar to those reported by Goodell, in which the child has been put aside as dead, after failure of the usual methods of treatment, and afterward has been found alive. These cases show that the prognosis is sometimes worse in appearance than in reality.

TREATMENT OF FRACTURES AT THE ELBOW-JOINT.

In a very interesting paper in the *Archiv für klinische Chirurgie*, vol. xxxvii, part 3, Dr. Carl Lauenstein, of Hamburg, advocates treating fractures of the humerus at the elbow-joint with the forearm in a position of extension, instead of, as is customary, in a position of flexion. He was prompted to this practice by studying the condition of the elbow-joint in the person of a patient who died within a year after being treated in the usual way. The specimen showed that flexion of the arm had been secured at the expense of the fragments, and not in the joint.

This discovery led to further study of the anatomical conditions present in fractures of this sort, and Dr. Lauenstein came to the conclusion that the ordinary treatment is almost inevitably followed by permanent deformity of the arm, and that this misfortune would be avoided if the arm were kept extended while the reparative process goes on.

These views appear to have been arrived at by independent observations on the part of Dr. Lauenstein; but many of our readers are no doubt aware that they are not new; for in 1880 Dr. O. H. Allis, of Philadelphia, published, in the Annals of the Anatomical and Surgical Society of Brooklyn, an admirable paper, illustrated by drawings which are closely paralleled by those in Dr. Lauenstein's paper, and advo-

cating the same method of treating fractures at the lower end of the humerus.

Both of these papers suggest a very important point in the management of these fractures, namely, the avoidance of a deformity which consists in altering the normal relation of the position of the forearm to that of the upper arm.

The method proposed has much in its favor; but we think that good arms can be secured without departing from the more convenient and comfortable method of fixing the forearm in flexion. For this, however, one point, which is often, we fear, overlooked, must be constantly borne in mind, namely, that in the normal arm the axis of the forearm is placed at an obtuse angle to the axis of the upper arm. The rectangular splint generally employed in the treatment of fractures at the elbow-joint almost of necessity brings the axis of the forearm into the same plane with that of the upper arm, and this can only be done by forcing the lower fragment into an unnatural position. The result is sure to be a permanent deformity, and more or less functional disability.

To avoid this, the splint should be made with a double angle: one in the vertical and one in the horizontal plane, and these should correspond exactly to the angles of the uninjured arm. With this precaution, results can be obtained which leave nothing to be desired, and there is no good reason why deformity and impairment of function should be looked upon as a natural consequence of fractures of the humerus at the elbow-joint. A correct knowledge of the normal position of the forearm in flexion, as well as in extension, and a fair degree of mechanical skill would prevent a large number of the unfortunate results after fractures of this sort, and those who do not feel safe in treating them with the arm flexed would do well to adopt the method so forcibly demonstrated by Dr. Allis and now supported by the later arguments of Dr. Lauenstein.

INTRAPERITONEAL CYSTOTOMY.

Among the interesting publications on the subject of supra-pubic cystotomy which have recently appeared is one by Professor Rydygier, of Cracow, cited in the *Wiener med. Presse*, September 30, 1888, in which he recommends opening the bladder by an incision through the part of it which is covered by peritoneum. He is prompted to adopt this method by consideration of the difficulty of obtaining union by the first intention after an ordinary supra-pubic cystotomy, and of the tendency of the peritoneum to adhesive inflammation. In order to test the applicability of this plan, Rydygier made a series of experiments on dogs, and then, last December, performed the operation on a boy thirteen years old, who suffered with stone in the bladder. The result of this operation, and of several others on older patients, has been entirely satisfactory, union by first intention having followed in every case. This experience leads him to propose opening the bladder through the peritoneal cavity for the removal of vesical calculi, or of neoplasms in the bladder, as a formal method.

There can be no doubt that the dread of wounding the peritoneum, which has long been regarded as one of the greatest dangers in supra-pubic cystotomy, has always been much exaggerated; both in respect of its frequency and in respect of its consequences.

In 1875, Dr. Dulles, in analysis of the largest number of cases ever collated—at that time—found but three in which the peritoneum was said to have been "cut" or "burst," and but six in which death was attributed to peritonitis. These all occurred before the operation of supra-pubic lithotomy had attracted the attention which it has secured during the last thirteen years. At the present day, it may be said that an involuntary wounding of the peritoneum may always be avoided by a proper combination of anatomical knowledge and manual

dexterity; and, in the present status of abdominal surgery, an unavoidable wounding of the peritoneum can hardly be regarded as a formidable accident, or as one which would materially increase the slight inherent risks of a supra-pubic cystotomy.

A deliberate opening of the peritoneum is a somewhat different matter. Rydygier is not the first surgeon who has operated in this way. As long ago as 1723, Prœbisch is said to have opened the peritoneum intentionally in order to remove a stone from the bladder. In 1871, Mr.—now Sir—Joseph Lister undertook a supra-pubic lithotomy on a boy, in Edinburgh, and accidentally cut the peritoneum. His patient recovered so nicely that he soon after operated upon a man, and, relying upon his antiseptic methods, deliberately opened the general abdominal cavity and cut into the bladder where it is covered with peritoneum. This patient, however, died. In 1881, Langenbuch proposed opening the bladder through the abdominal cavity by a peculiar method *en-deux-temps*, which seems never to have been actually practised.

These facts are of historical interest in considering Rydygier's proposition, but they do not affect the credit to which he is entitled for placing the method of intra-peritoneal cystotomy on a basis thoughtfully planned, supported by experiment, and confirmed by actual experience on the human subject. Some acquaintance with the subject of supra-pubic cystotomy leads us to believe that the method suggested by Rydygier deserves the careful attention of surgeons, and that further experience may show that the bladder may be as safely opened through the abdominal cavity as through the prævesical tissues, and with a better chance of subsequent union by the first intention. Such a method would certainly be easier to carry out; and, if it proved successful in the hands of other operators, it would undoubtedly inaugurate a new era in cystotomy.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

TREATISE ON THE DISEASES OF WOMEN. By Alexander J. C. Skene, M.D., Professor of Gynecology in the Long Island College Hospital, Brooklyn, N. Y., etc. Illustrated with 251 Engravings and 9 Chromo-Lithographs. 8vo, pp. 966. New York: D. Appleton & Co., 1888.

This work is written from a clinical standpoint. The subjects of the anatomy, physiology and pathology of the female sexual organs are not elaborated—only enough is said about them to enable the student and practitioner to appreciate the natural history of the diseases of these organs and to treat them intelligently. A feature of the book is the insertion of reports of cases, placed at the end of each chapter, to illustrate the principles set forth in it; or, to represent a-typical or complicated conditions. There is an interesting chapter devoted to gynecology as related to insanity in women, and the section on the diseases of the bladder and urethra embraces a third of the volume. While this detracts from the proportions of the book, viewed artistically, it adds very much to its practical value.

The operation for the cure of fistula in ano, by careful denudation and suturing, is noticed favorably, as likely to bring about a cure and preserve continence of feces. A more than usually favorable prognosis is given in regard to the catarrhs of the uterus. The pipette is used to make intra-uterine applications instead of the applicator or the generally abandoned syringe. The intra-uterine stem pessary is in high favor with Dr. Skene, but its dangers are sufficiently dwelt upon. He also relies upon the hypodermic needle and the larger aspirator more than the progressive surgeons of to-day; and he has not joined those who regard the tapping of ovarian or other intra-abdominal cysts as unjustifiable except under rare conditions. Early ovariotomy is not insisted upon.

The author's treatment of flexions is striking. Flexion is considered a deformity, and, in the chapter devoted to its consideration, only flexions resulting from error of development and from inflammatory or degenerative disease of the parenchyma of the womb are discussed.

The chapter devoted to the anatomy, physiology and injuries of the pelvic floor is in most respects admirable. The author still talks about the "perineal body," but this we can forgive him, since he makes it plain that this so-called body is simply a part of the supporting segment of the pelvic floor; that its functions do not depend on its being a wedge of indifferent tissue interposed between the outlets of the rectum and vagina, but upon the fact that the muscles of the pelvic floor, levator ani, transversus perinei, bulbo-cavernosus, and sphincter ani, centre here. This important fact is well brought out and the injuries of these structures are considered; and not lacerations of mere skin, mucous membrane and connective tissue. The descriptions of the various operative procedures for the cure of these injuries we think could have been made plainer, and the operation recommended for so-called incomplete laceration is not the one we have considered best; but the principles laid down are so sound and true that the practitioner fully imbued with them cannot but obtain good results.

The subject of the dislocations of the uterus is presented better than in any work with which we are familiar, excepting perhaps Hart and Barbour's Manual.

In the preface it is stated that unsettled questions are omitted. Perhaps this accounts for the chapters on diseases of the ovaries, pelvic peritonitis and pelvic cellulitis. Had these been written five years ago they would be considered excellent. But the advances made since that time are only dimly hinted at, and not clearly presented.

Lack of space prevents a consideration of the work in further detail. We regard the book as one of the best extant on gynecology, and especially so for the student and general practitioner; and we think that but few specialists can read it without profit as well as pleasure. The illustrations are of more than usual excellence, and many of them are original. The printing also is good, but the paper is rather poor.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

156. Chronic Pyelitis, Successfully Treated by Kolpo-Uretero-Cystotomy. Irrigation of the Pelvis of the Kidney, and Intra-Vaginal Drainage. By Nathan Bozeman, M.D., New York. From the *Amer. Journal of the Med. Sciences*, March and April, 1888. 19 pages.

157. Renal Tenesmus. By Nathan Bozeman, M.D., New York. From the *Medical Record*, Aug. 4, 1888. 36 pages.

158. The American Hip-Splint. By Dr. A. B Judson, New York. From the *Transactions of the Ninth International Med. Congress.* Vol. III. 4 pages.

159 The Electro-Magnet in Removal of Steel from the Interior of the Eye. By Alvin A. Hubbell, M.D., Buffalo, N. Y. From the *Buffalo Med. and Surg. Journal*, July, 1888. 8 pages.

160. Tubercular Diathesis. By W. C. Chapman, M.D., Toledo, Ohio. From the *Columbus Med. Journal*, July, 1888. 9 pages.

161. Heredity. By James Thomas Learcy, of Tuscaloosa, Alabama. From the *Transactions of the Med. Association of the State of Alabama.* 16 pages.

162. Some of the Advantages of the Union of Medical School and University. By William H. Welch, M.D., Baltimore, Md. From the *New Englander and Yale Review*, September, 1888. 19 pages.

156. This paper by Dr. Bozeman contains a portion of what appears in his more extensive paper read before the Ninth Inter. Med. Congress, and already noticed as pamphlet No. 154, in these columns. It is based upon his study of and experiences with a patient whom he treated successfully by the method here described, and is admirably illustrated.

157. In this paper Dr. Bozeman discusses a curious condition which he distinguishes from what is commonly called renal colic, and which he states to be a "frequent result of chronic cystitis and ureteritis, in contradistinction to pyelitis, the usual result of urethrocele, cystitis and ureteritis." He also describes fully the method of treatment which has proved most satisfactory in his experience.

158. Dr. Judson's pamphlet contains a short, but excellent, historical sketch of the invention of the American Hip-Splint, and explains how it is entitled to the name. In addition he gives some important practical points in the early diagnosis of hip-joint disease, and one or two hints in regard to its treatment. His pamphlet also contains three figures showing certain modifications in the hip-splint which he has designed.

159. Dr. Hubbell describes the use of the electro-magnet for the removal of fragments of steel from the interior of the eye, and a form of magnet, of unusual power, which he had made by an electrician. This instrument is of convenient size, and its efficiency has been proved in two cases. His pamphlet contains an illustration of the magnet, and good description of the way in which this method of extraction should be carried out.

160. Dr. Chapman's paper, which was read before the Ohio State Medical Society, contains a thoughtful and interesting study of phthisis, and lays great stress upon the hereditary tendency of certain individuals to develop the disease. The author inclines to the belief that it is a mistake to apply the term solely to cases in which tubercle bacilli are found, and that other micro-organisms may set up the process of wasting and destruction of the lungs which is popularly called consumption. We can heartily commend his pamphlet to the attention of our readers, who will find it full of instructive and suggestive thoughts.

161. Dr. Learcy's pamphlet contains a study of the principles of generation, and an argument for the view that physical and mental characteristics are the result of inheritance, and that their cultivation depends upon repeated action. The author seems to be a pronounced believer in the doctrine of evolution, and states his belief that man was originally a-sexual, the female being the type of the species and man a variation from it.

162. In this address, which was delivered at Yale University, June 26, 1888, Dr. Welch makes an able argument for the union of medical schools with universities, or rather, for the formation of medical departments in universities, as an integral part of them. The example of German medical teaching, and the high development of the science of medicine in Germany, furnish a motive to much that he says; and all that he says is with the object of elevating the standard of medical education in the United States.

We cannot here repeat or even summarize his argument; but all the friends of higher medical education in the country would do well to study it for themselves.

—The annual banquet of the Ex-Resident and Resident Physicians of the Philadelphia Hospital, Blockley, was held at the Colonnade Hotel Dec. 4. Dr. Elmer, of Bridgeton, N. J., was elected President for the ensuing year.

CORRESPONDENCE.

Prevention of Conception.

TO THE EDITOR.

Sir: It seems to me that this subject is an important one and that it deserves careful consideration from medical men. We know that many, in all classes, are experimenting for the purpose of limiting the number of offspring, and that many women who marry nowadays either have a preventive which they intend to try, or hope to find one.

An inquiry into the cause for this state of affairs is certainly within the province of a medical journal. There can be no doubt of the desirability of preventing conception in cases of deformed pelvis, and all anomalies of the body which make delivery impossible; but I am not so sure of the desirability of preventive measures in all cases of syphilis, tuberculosis, deaf-mutism, derangements of nervous equilibrium, etc. When persons known to be subject to these disorders are allowed by law to enter into an alliance, the primary object of which is to perpetuate the species, the physician is not bound to interfere after the agreement is binding, unless the case is an aggravated one. The reason for such an opinion lies in the fact that preventive measures, if applied promiscuously to even one class of cases, would spread too far. Women even more than men dislike toil, hardship and suffering; and if it were once perfectly clear to the female mind that she is at liberty to limit this most disagreeable duty she would do it. The talk about mother-love being sufficient to make the human female endure the ordeal of delivery in order to become possessed of offspring is nonsense. Her nature may be altogether changed by circumstances, so as to bear but slight resemblance to what we are accustomed to consider natural. Witness the character of the Roman women who could calmly see men eaten by wild beasts, or butchered by their fellows!

On the whole, man cannot improve upon the Creator's plans for populating the earth. Women seek relief from the burden, because their physical suffering is too great to be borne. If the wife cannot influence the husband to have mercy on her in this respect, the physician should not be expected to atone for his brutality, and practically to cultivate his evil passions instead of relieving both of a grievous burden.

Women's health is an argument strongly urged; but conception may be a means of obtaining at least partial rest for the sexual function. If immunity from conception were guaranteed, women would be more willing to permit sexual indulgence. The evils of excessive venery would then become factors in the lives of both husband and wife. In this discussion the unfortunates who indulge their appetites out of wedlock receive neither countenance nor consideration, and no scheme for the conduct of married life concerns them. Yet they are made of the same flesh, and feel the same anguish, and present as many difficulties in the time of gestation as their virtuous sisters. The harlot, with no chance at all to make her offspring comfortable and happy, is consigned to torment, while it is proposed that those who have many kind offices to bestow upon their progeny should be told how to keep them unborn.

Perhaps it will sound like heresy to say so; but observation teaches that the greatest source of ill-health in mothers is not the bearing of children, but the way they spend their lives. How many physicians can think of half a dozen women who make a proper use of all the means within their power to make their bodies perfect? When an effort is made to have a patient, who complains that bearing children is exhausting her vital strength, or who really needs a tonic to the nervous system for some other reason, carry out a hygienic plan of treatment, the result is often far from satisfactory. Children were once considered necessary to furnish material to replenish the decimated ranks of armies; to cultivate the soil, to found colonies; and their appearance was welcomed with joy. The patriarch's wife said: "*Give me children* or I perish." The American wife cries: "*Give me no children lest I perish.*"

During the past week the writer attended a young woman in her third confinement. She has been married five years, and is the mother of three living children, and has had one miscarriage. Her husband is a healthy young farmer, and she is small, though well proportioned. After her confinement was over she said: "Now, Doctor, what shall we do to keep from having babies after this?"

In a case like this, what should be done? It is sincerely to be hoped that the present discussion may give us more light, if we are not justified in absolutely refusing to prescribe a prevention for conception.

Yours truly,

JAMES E. FREE, M.D.

Benezett, Pa.,

Treatment of Boils.

To the Editor.

Sir: In the Reporter, Nov. 17, 1888, I notice an article on "A Crop of Boils," by Dr. William M. Capp, in which he gives the pathology of the affection in a very scientific way. This leads me to believe that he understands the nature of boils. But his treatment is too skillful and overlooks the fact that a faulty nutrition is the cause of boils; if he will direct his treatment to the organs of digestion and introduce iron into the blood in such a way that it will be assimilated and build up broken-down tissue, he will, I think, succeed in curing boils.

I beg leave to suggest the following treatment:

℞ Tinct. ferri chlor. . . . . gtt. xv
Liquor potassii arsenitis . . . . . gtt. iii
Aquæ . . . . . f℥ ss
Take at a dose after each meal.

Use locally carbolized camphor, and a poultice when there is much inflammation. Also give small doses of Epsom salt to prevent constipation. This treatment will add another to the list of "sure cures."

Yours truly,
T. L. Craig, M.D.

Benedict, Kansas,
Nov. 20, 1888.

Erratum.

The last two lines on page 645 of the Reporter, November 24, should read: "The Medical and Surgical Reporter for Oct. 27," instead of for "Nov. 3."

Yours truly,
Ernest C. Helm.

Beloit, Wis.,
Nov. 27, 1888.

—The Board of Health of Jacksonville, Fla., has adopted resolutions permitting all persons to enter the city in day-time after Dec. 10, and all refugees to return without restriction by Dec. 15.

—Dr. W. B. Dorsett communicates to the *Weekly Med. Review*, Nov. 24, 1888, an account of a case in which a baby at birth had the lower two-thirds of the stomach and all of the small intestines, as far as the ileo-cæcal junction, including the greater portion of the mesentery, entirely outside of the abdominal cavity. An operation was done for the deformity, but the child died.

Notes and Comments.

Sand-Bur in the Larynx.

Dr. William B. Dewees reports the following case in the *Kansas City Med. Index*, Oct., 1888.

Miss B——, 21 years old, while out walking with companions, picked several sand-burs from her dress, which in turn fastened to the kid glove on her hand, from whence she endeavored to dislodge them with her teeth. Engaged in this act, a sudden, unguarded inspiration carried one of the burs into her throat, lodging in the larynx. The immediate suffering and excitement promptly brought the father with a carriage to the rescue, who forthwith conveyed her to my office. A careful, thorough examination, aided by Tobold's large reflector and lamp, proved vain to locate the foreign body. Localized pain within the larynx, an irritative, hacking cough, painful deglutition and hoarseness of voice, which was scarce above a whisper, constituted the leading train of symptoms. All considered the case as manifesting no immediate seriousness, and accordingly an expectant course of treatment was adopted, which consisted in advising absolute quiet in regard to speech and spraying the larynx and adjacent parts twice daily with a ten per cent. solution of cocaine.

The case progressed favorably, nothing in addition to the foregoing symptoms manifesting itself, except a blood-tinged expectoration, until the tenth day, when, soon after rising in the morning, a violent fit of coughing was invoked, which brought forth the *entire bur*, imbedded within a coating of mucus. Immediately all suffering ceased, the voice gradually regaining its normal tone.

Latent Carcinoma of the Dura Mater.

At the meeting of the Berlin Medical Society, October 11, 1888, Dr. Loewenmeyer exhibited a cancer of the dura mater, which had produced three large perforations in the skull. The specimens were removed from a man 44 years old, who died of carcinoma of the lung. A strange thing is that the tumor of the dura mater, in spite of the considerable destruction which it had made in the skull, had not produced the least symptoms; and it was a great surprise to meet with it at the autopsy. Large tumors of the dura mater are nearly always sarcomas; but in this case the structure of carcinoma was as nice as possible.—*Bulletin Médical*, October 21, 1888.

Glycerine Enemata in Children.

In a communication to the *Lancet*, Nov. 10, 1888, Mr. G. A. Carpenter says that during the past four months glycerine enemata have been used at the Evelina Hospital to the exclusion of purgatives, for the treatment of constipation among the patients. He gives a tabular statement of the results obtained from 214 injections given to 63 children, and says that an action of the bowels followed in five minutes or under in ninety-five instances; in ninety in thirty minutes or less; while in four the time was not recorded. Fifteen injections failed to relieve within the above-mentioned times, and intervals varying between thirty-five minutes and eleven hours were noticed in these. If one analyzes, he says, the fifteen instances in which more than thirty minutes elapsed before any action of the bowels took place, it will be noticed that they occurred in ten children, of which the most marked, as regards the length of time elapsing, are the cases of two special patients. It is worthy of note, he says, that five of the ten cases were suffering from tubercular disease in some form or another; three were osteotomies, and in consequence restrained from movements; one was a fractured femur treated in a double Bryant's splint; and, lastly, one was a case of chorea, in which, as is often the case, constipation was marked. Seven of the ten children were girls.

Coming to the failures, he finds that an osteotomy (in a girl) was accountable for a want of success and a return of the injection on three occasions; but in this child the injections were attended with success on eighteen different occasions, the bowels being relieved with one exception within the half-hour. In a case of tubercular disease of the spine, the first glycerine enema acted efficiently, an evacuation of the bowels occurring in five minutes; but a dose of three drachms failed later on, and a repetition gave no relief. This also was a girl. A knee excision (in a girl) shows one failure and three successes, the average time required for the injections to act being thirteen minutes. In the case of a child suffering with meningitis, the enema was returned, and not repeated. In a child with "pulpy" elbow, there was one failure and two successful injections. A case of suppuration of the antrum, he says, is responsible for one failure and one success. Five of these children were girls, and one was a boy. In all of the failures it will be noted that the bowels were capable of responding to glycerine stimulation at one time or another, and in no case was there complete failure.

As regards the quantity of glycerine used for an enema, he states that one drachm was given to 156 cases; a drachm and a half to forty-eight; two drachms to seven; and on two occasions three drachms were injected. In 154 instances the injections were followed by normal motions; in twenty-six the motions were loose; in eighteen they were of more than natural consistency; in six the enemata were followed by scybala; and in ten they were either returned or failed to act. In no instance were the enemata attended with unpleasant symptoms, either locally or constitutionally.

Creoline.

Dr. L. Lichtwitz, of Bordeaux, in a communication on creoline, in the *Bulletin Médical*, September 30, 1888, concludes that creoline is a disinfectant (deodorant) superior to other agents, and that whenever it obviates bad odors formed in the nasal or buccal cavities, or in the ears—from ozæna, ulcerated malignant tumors, fetid otorrhœa, etc.—it should be employed. It diminishes the pathological secretions from atrophic pharyngo-rhinitis, "fibrinous" rhinitis, and otorrhœa. It is a powerful antiseptic and easy of application; being non-toxic, it is preferable to other antiseptics.

[This estimate of the value of creoline as an antiseptic is probably hasty. Other experimenters have questioned its value, and have shown that it sometimes produces toxic effects similar to those caused by carbolic acid. It is clear that it should be used only with caution.—Editor of the REPORTER.]

Electric Prostration.

Several cases of this new malady are reported from Creusot, France. It affects workers under electric light. The light exceeds 100,000 candle power, and it appears that it is this excess of light, and not the heat, which produces the nervous symptoms. A painful sensation in the throat, face, and temples is first noticed, then the skin becomes coppery red, and irritation is felt about the eyes; much lachrymation ensues, and these symptoms then disappear, whilst the skin peels off in five days. The effects are comparable to those produced by walking over fresh snow in the sunlight, and may be regarded as a sort of "sun-burning."—*Lancet*, Oct. 27, 1888.

Differential Diagnosis of Twisted Pedicle.

An interesting discussion took place at the British Gynæcological Society recently, on the means of distinguishing between a twisted pedicle in ovarian cyst and rupture of an ectopic pregnancy. The diagnosis is one which few practitioners would care to attempt, but it is in reality fairly simple, though in this, as in other intra-abdominal affections, the surgeon is exposed to surprises on opening up the cavity. The collapse in rupture of extra-uterine gestation is sudden and complete, the tumor, if any has been perceived, has disappeared, to be replaced by symptoms of internal hemorrhage and hæmatocele, and the pain is sharp. In twisted pedicle, on the other hand, the symptoms come on slowly, and the abdominal tenderness is extreme. The tumor is tenser than ever. As pointed out by Dr. Heywood Smith, the pulse may afford some help in arriving at a diagnosis, the hemorrhage being limited to the cyst in the one case, but practically unlimited in the other. In extra-uterine pregnancy the symptoms rapidly run on to a fatal termination, unless relieved by abdominal section; whereas in the other, they may pass off in the course of a week, and the tumor become smaller. An important point in the diagnosis is evidently the presence of symptoms pointing to pregnancy, though their absence is not equally significant.—*Medical Press and Circular*, Oct. 31, 1888.

Acute Obstruction of the Bowels.

Dr. Coppens, Chief of the Surgical Clinic in the Lille Faculty of Medicine, has a paper on acute obstruction of the bowels and peritonitis from perforation, in the *Archives générales de Médecine*, October, 1888. He concludes that, of all varieties of false obstruction, peritonitis from perforation is the only one that it is possible to confound with acute obstruction of the bowels—an error which has been often committed. The diagnosis between the two affections is essential before treatment can be thought of. This diagnosis, he says, is possible. The most important differential points are drawn from an examination of the temperature, and of the degree and mode of appearance of the meteorism. Contrary to what has been maintained hitherto, he asserts that it is in peritonitis, and not in strangulation, that tympanites is met with most frequently and in the highest degree. If it is possible to distinguish acute intestinal obstruction from false, it is nearly always impossible, in the case of true obstruction, to determine its variety. But this, he says, is of no importance whatever from the point of view of treatment. He regards it as dangerous to resort to mild measures for too long a time. The abdominal incision, he says, should be median and large enough to ensure rapidity and ease in exploration.

Saccharine.

The *Lancet*, Oct. 27, 1888, says that the true position of saccharine is becoming somewhat hard to define. Its employment in the preparation of many substances liable to duty has already been prohibited, but this course of action was quite compatible with the possession of the most harmless properties. In a recent text-book on therapeutics, the author, when dealing with saccharine, appended the following disparaging foot-note: "The present is probably as good as any other place in the book to notice a substance whose use in practical medicine depends upon its lack of medicinal properties." Still, of late there have appeared several paragraphs in various journals referring to the report of a commission of Paris doctors, and their adverse verdict has already served to disquiet many diabetics, who had hitherto placed full confidence in saccharine. In the abbreviated form in which it has reached us, this report does not amount to very much. It starts with the assumption that saccharine is antiseptic; but this fact rests upon a very slender foundation—its power of retarding putrefactive changes in the urine eliminated during its employment. The main conclusions of the French commission are that it seriously troubles the digestive functions and increases dyspepsia, and should be prohibited as an article of food. These statements are not in accordance with those of very many previous observers, who have studied the action of saccharine, and found it to be mainly negative. Large quantities have been taken by men, and have been administered to animals, without causing any symptoms of any kind. The report merits attention, although it is so widely at variance with previous experience that it seems probable that some oversight has led to these conclusions.

For a succinct statement of the properties and uses of saccharine, our readers are referred to an Editorial in the Reporter, June 23, 1888.

NEWS.

—Typhoid fever is reported to be epidemic in Brooklyn, New York.

—Dr. John H. Larrabee, the eldest son of Dr. J. A. Larrabee, died in Louisville, Nov. 17, 1888.

—The steamship Bolivia arrived at New York, Dec. 2, from Gibraltar, with smallpox on board.

—Naples is to have a new University building at an estimated cost of about 16,000,000 francs.

—The physicians of Lansing, Mich., are said to have combined to protect themselves from patients who do not pay.

—Typhoid fever is prevalent in Providence, Rhode Island. Seventy-five cases are said to have been reported.

—There was one case each of variola, varioloid, and scarlatina at the Municipal Hospital of this city during November.

—It is stated that the importation of saccharin and substances containing it has been forbidden in France and Algeria.

—Pleuro-pneumonia has developed among the cattle in Monroe County, New York. One hundred and fifty animals are said to have been killed.

—Dr. W. B. Boyd, of Bloomington, Illinois, committed suicide Nov. 30, by shooting himself. He is said to have been in poor health for some time.

—Dr. G. A. Slocomb is credited with having safely delivered a woman in Millbury, Mass., of four girl babies, all of whom are alive, though one is very delicate.

—Mr. Montagu Perceval states in a note to the *Lancet*, Nov. 17, 1888, that he has found antipyrin in two-grain doses every hour very useful in laryngismus stridulus.

—Two new cases of yellow fever were reported in Jacksonville, Fla., Dec. 2, but no deaths. The total number of cases up to that time was 4669; total number of deaths 410.

—Dr. J. Cheston Morris appeared before the Finance Committee of Councils of this city, Dec. 3, to advocate the appropriation for a milk inspector, to act under the supervision of the Board of Health.

—A woman living in Burlington, N. J., made a mistake in taking a dose of medicine recently, which nearly cost her her life. She desired to take some cough mixture, but, instead, picked up a bottle and took a teaspoonful of tincture of iodine.

HUMOR.

"I AM ON MY WAY HOME, Doctor," said a citizen who was after some free advice, "and I'm tired and worn out. What ought I to take?" "Take a cab," replied the intelligent physician.—*Worcester Gazette.*

CITIZEN: "What are you doing with that man?" Policeman: "I have just arrested him." Citizen: "But he's as deaf as a post." Policeman: "He'll get his hearing before the magistrate."—*Harper's Bazar.*

DISCHARGED FOR CAUSE.—"Why did you leave your last place?" "Sure I worr discharged for doin' well, mum." "Discharged for doing well? Why, where were you?" "I worr in the harspital, mum."—*Harper's Bazar.*

YOUNG DOCTOR (to hospital superintendent)—"I want no interference, sir, with my directions. I know my business. I have walked all the hospitals of London and Paris." Superintendent—"You may have walked foreign hospitals, sir; but you'll find that I run this one."

OLD LADY—"You seem to have a cold, sir." Stranger—"Yes, madam." Old Lady—"Well, I tell you what to do. Jes' go home and put your feet in a tub o' hot mustard-water an'—" Stranger (gruffly)—"That's fine advice to give a man with a cork leg; now, ain't it?"

METEOROLOGICAL ITEM. — Miss Bunker Hill—"Do you have much Indian summer in Colorado?" Major Wester—"Yes, we have a great deal more Indian summer than you do here in the East." "I wonder why that is so?" "Because we have got more Indians, I reckon."—*Texas Siftings.*

WASTEFUL.—"But what an awful lot o' money those high-toned travelers waste for drink," said Uncle Abner, as he laid down his newspaper. "A man who'll pay a hundred dollars for a saloon passage to England when he can get it in the steerage for twenty is a slave to rum—that's what I say!"—*Life.*

THERE HAD BEEN A RUNAWAY; a pair of horses were down, a carriage smashed to pieces, and the driver and a lady lay groaning on the grass with their hurts. The street-car stopped and many got off to render aid. Among those who stood on the rear platform were two ladies, one of whom held up her hands and exclaimed: "Mercy on me! but what an awful, awful affair! How long did you say you boiled your grape jelly, Mrs. Smith?"

Cod Liver Oil deteriorates rapidly when exposed to light. The North Cape is carefully protected from light from the time of its production, and will remain fresh and sweet indefinitely.

IMPORTED BY

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

FOR THE INSANE.

CINCINNATI SANITARIUM.

PRIVATE HOSPITAL AND RESIDENCE.

(Incorporated 1873.)

Proprietary Interest Strictly Unprofessional.

Both sexes and all classes of mental and nervous diseases provided for.

Forty minutes by rail from C. H. & D. depot, Cincinnati. Address,

ORPHEUS EVERTS, M.D., Sup't.

COLLEGE HILL, OHIO.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

THE SURGICAL IMPORTANCE OF STRICTURES OF LARGE CALIBRE.[1]

BY J. WILLIAM WHITE, M.D.,

CLINICAL PROFESSOR OF GENITO-URINARY SURGERY IN THE UNIVERSITY OF PENNSYLVANIA; SURGEON TO THE PHILADELPHIA AND GERMAN HOSPITALS.

There is no necessity at the present day for an argument in favor of the existence of the slight contractions of the urethral canal known as strictures of large calibre. The work of Dr. Otis in this country, Mr. Teevan in England, MM. Guyon, Terrillon and others in France has shown conclusively that such contractions may be of considerable importance; and the general phenomena associated with them now constitute a group familiar to every genito-urinary specialist. The patient will present himself with the following symptoms, often so slight that he is inclined to apologize for seeking professional advice, and sometimes elicited only by careful questioning. He will have noticed that in the mornings the lips of the meatus urinarius are glued together, and that on separating them a drop of whitish, opalescent fluid makes its appearance. Micturition will be found to be slightly more frequent than usual, and the patient will particularly describe a slight haste and urgency to begin the act, which in its actual performance is a little slow and somewhat imperfect. At the end of urination, unless he pays especial attention to shaking and stripping the penis, there will be a dribbling of a certain amount of urine, varying from a few drops to a drachm or two. He will often complain of a dull aching sensation in the lumbar region and of a similar feeling in the hypogastrium, or occasionally of a neuralgic pain in one or both testicles. I have elsewhere explained[1] what seems to me the *rationale* of the development of these symptoms, and I reproduce a portion of that explanation here as a fitting introduction to a few cases which I desire to place on record.

To account for the symptoms above mentioned, and for their cause, there are certain general physical and physiological laws which should be recalled. Persistent irritation, such as that which results from frequent or protracted attacks of gonorrhœa, causes at any given point in the body an increase in the fibrous tissue of that region, and the deposit or development of new tissue of a similar character. This is especially true of mucous and submucous surfaces, and still more particularly of the urethra, which, by its anatomical peculiarities, offers peculiar facilities for the production and organization of inflammatory products. Such a deposit, occurring in the submucous structures around the urethra, interferes to a greater or less extent with the lumen of that canal and thus constitutes a stricture. Once deposited, here as elsewhere throughout the body, this new tissue tends to contract more or less steadily and continuously. This is in consonance with a well-known pathological law; and the contraction is no more noticeable here than

[1] A translation of this article is published in the current (November) number of the *Annales des Maladies des Organes Génito-Urinaires*, edited by M. Felix Guyon.

[1] *International Encyclopædia of Surgery*, Vol. II.

when it occurs in the intertubular spaces in interstitial nephritis, strangulates and destroys the parenchyma of the liver in cirrhosis, produces induration and bronchiectasis in chronic pneumonia, limits the movements of inflamed joints, distorts or deforms after burns and scalds, or in any of the many possible directions exerts its power in the production of disease. We have, then, it must be admitted, in urethritis, a sufficient cause for the production of a condition which tends gradually to diminish the size of the urethra and to interfere with its dilatability.

In studying the effect of this condition in producing the symptoms that have been detailed, certain other physiological laws must be taken into account. Habit is a powerful agent in facilitating and controlling the functions of animal life. Illustrations of this fact in other systems than the genito-urinary are frequent and familiar. But to take up the case in question, it is safe to say that in a healthy adult, a certain equilibrium has been established and maintained between the usual efforts and powers of the bladder as an expulsive organ, and a certain average amount of resistance which must be overcome before it can empty itself. At the age of twenty-one years, this adjustment of force depends upon a large number of previous distinct acts of micturition. This balance between the force of expulsion and its work cannot with impunity be disturbed, and even a slight interference with the calibre of the urethra tends to produce such disturbance.

Apart from the proclivity to muscular spasm in the neighborhood of and behind every stricture, this interference with the action of the bladder arises from the encroachment of the new deposit upon the urethral calibre. It is a law of hydrostatics that, if a current of liquid be passed along a tube, a certain degree of friction proportionate to the amount and velocity of the current and the size of the tube takes place between the walls of the latter and the liquid; if the tube be narrowed at any one place, the friction is increased at that point, and, to avoid a diminution in velocity, the propulsive force behind the liquid must also be correspondingly increased.

Still another point must be mentioned before I turn to the group of symptoms, the occurrence of which after so many cases of gonorrhoea I shall endeavor to explain. The act of micturition is one requiring for its perfectly normal performance: first, the relaxation of certain muscles to secure patency of the urinary channel; and, next, the thorough and complete contraction of those muscles to produce entire evacuation of the contents of the passage. The latter portion of this act is accomplished by the contraction of the circular muscular fibres which surround the urethra, and which, in a healthy condition, serve to bring and retain its walls in close apposition during the intervals of urination. The submucous deposit which increases the friction of the stream of urine at any point, also interferes with the accurate closure of the canal by those muscles whose action is impeded, and whose structure itself is in part often invaded, and as a consequence we have imperfect emptying of the urethra at the end of urination. Finally, if in addition we recall the intimate nervous connection of the urethra with all the viscera of the abdomen and pelvis, and with the walls of those cavities, and the reciprocal relations that exist between them, we are in a position to sum up the relation of the pathological and subjective phenomena as follows:

The increased friction and resistance resulting from even a slight fibrous periurethral deposit disturb the normal relations of the bladder, and, by rendering it irritable, bring on one of the common symptoms of stricture, frequent micturition. The imperfect closure of the tube, the muscular action of which at the point of deposit is materially interfered with, causes the equally imperfect expulsion of the last drops of urine, and produces another characteristic symptom—dribbling at the end of micturition. The retention and decomposition of these last drops, together with the abnormal friction between the stream of urine and the urethral walls, gives rise to a subacute inflammation of the mucous membrane, accompanied with a catarrhal or muco-purulent discharge, constituting the condition of gleet; while pains in remote organs and situations, notably in the lumbar and hypogastric regions, are developed by reflex irritation transmitted from the area of inflammation.

This relation of causes and effects has been in the main accepted as correct by the profession for many years. Probably no one denies that in certain strictures in which the urethral calibre is markedly diminished, the connection between the pathological changes and the observed indications is about as has been stated. The differences of opinion which now exist are chiefly as to the amount of urethral contraction which is sufficient to produce noticeable effects.

That every urethral coarctation following on urethritis must at some time have been a stricture of large calibre, is self-evident, but just when such a stricture becomes an active pathological factor, and is able in the manner indicated to give rise to symptoms, is an unsettled point. Indeed, it is not probable that it ever can be definitely determined. The idea that any particular fixed calibre represents the normal condition of the urethra has long ago been abandoned, the observed variations of that canal being such that no special dimensions can be assigned to it as representing the precise dividing line between health and disease. The old method of regarding the size of the meatus as an indication of the normal calibre of the canal behind it, is also unquestionably fallacious, it having been conclusively shown that no more definite relation exists between them than between any other mucous canal and its corresponding outlet—the mouth and the œsophagus, for example, or the anus and the sigmoid flexure. That there is a certain correspondence between the size of the urethra and that of the flaccid penis, is true, the calibre of the one increasing with the circumference of the other, but that this ratio is present in any absolutely unvarying manner, has not yet been demonstrated. At the most, the size of the penis may be said to furnish a general indication of the urethral dimensions, but one which is approximate merely. On the other hand, it has been shown that there are usually certain normal variations even in the spongy portion, which is now claimed with much show of truth as the most common seat of pathological contractions, and that it is impossible with any of the means at our command to distinguish between these natural irregularities and coarctations of equal calibre due to incipient stricture.

An illustration of what I refer to is found in the following case: A muscular and apparently robust man, aged about 55 years, was admitted to my wards in the Philadelphia Hospital, suffering from a leg-ulcer. No urinary trouble was suspected until he was subjected to an examination for the purpose of verifying a theory to which I shall presently allude. He was then found to have a coarctation at the distance of four and a half inches from the meatus. There were no marked subjective symptoms whatever: micturition was possibly a little too frequent, and was not quite complete, a slight dribbling following the flow of urine; there were obscure lumbar and hypogastric pains, and occasional neuralgia of the glans penis; but these facts were only elicited after careful questioning. A No. 28 steel sound passed into the bladder without the slightest perceptible difficulty, but the patient complained of pain extending from the peno-scrotal junction to the perineum. An examination with a bulbous bougie, No. 24, revealed a stricture situated in the spongy portion of the urethra at the point mentioned, about four and a half inches from the meatus; No. 26 bulbous could be passed only with great trouble.

Dilatation was commenced, but an attack of some intercurrent disease—pneumonia, I believe—caused the patient to be transferred by one of my internes to the medical ward, where he soon after died. At the autopsy I carefully removed the genito-urinary organs, on the appearance of which I have the following notes: The penis was of average size, the pendulous portion measuring about four and three-quarters inches in length, and a little over three inches in circumference. (This would have fixed the normal calibre of the urethra, according to Dr. Otis's standard, at about thirty-one millimetres.) Upon dividing it along the dorsum a band of fibrous structure was seen almost encircling the urethra four and a half inches from the meatus; extending from a point a little anterior to this back to the bulb of the corpus spongiosum and to the crura of the corpora cavernosa was an area of intense congestion, which persisted even after maceration of the specimen in chloral solution for two weeks, and was then plainly noticeable across the room at a class demonstration; the bladder was dilated and hypertrophied and the ureters slightly dilated; the kidneys were healthy; there was no enlargement of the prostate. Two small patches of ulceration existed on the floor of the membranous urethra, each measuring about two lines in diameter. A microscopical examination of the constricting band was made by Dr. Shakspeare, Pathologist to the Philadelphia Hospital, with the following result: "The section which I made of the stricture submitted for examination by Dr. White included the mucous and submucous tissue. Longitudinal sections were made after the specimen had been hardened in alcohol. These, after staining in carmine and mounting in dammar, exhibited under the microscope a great increase of the fibrous portions of the submucous tissue. Among the fibrous bundles were numerous typical, curly, elastic fibres.

"It was also noticeable that the walls of the capillary vessels running toward the

mucous surface were very thick and fibrous (sclerosed). The inflammatory processes were in the last stages, as was evidenced by the sparseness of cellular elements scattered throughout the fibrous portion."

This case is, in my opinion, one of a large class formerly often overlooked, and still neglected or misunderstood by those practitioners who adhere to the old methods of examination.

As lately as 1875 Sir Henry Thompson said: "When a young man consults you for certain troubles relative to which you desire to learn whether urethral obstruction be a cause or not, do not be tempted for an instant to adopt so unnecessary a course as the introduction of very large instruments or instruments with huge bulbs at the end of them; but simply take a flexible English gum-elastic bougie well curved toward the point, with a blunt end not larger as a rule than number ten or eleven of our scale, and pass it very gently and slowly into the bladder. If it goes easily—above all, if it is withdrawn without being held and slides out with perfect facility—take my word for it he has no stricture, and, *quoad* obstruction wants no use of instruments whatever." He says elsewhere, however: "With the bulbous bougies (various sizes) you may determine the existence of any narrowing in any part of the urethra with great accuracy, and for many years I have never operated without employing them carefully beforehand." I infer from the context of his lectures on the urinary organs, that he refers in this last remark rather to the locating of strictures already discovered than to their original detection. The value of the *bougie à boule* in the diagnosis of strictures is now so universally recognized that no argument in its favor seems necessary, but I desire *en passant* to call attention to one source of error which is associated with their use in the deep urethra and which is not infrequently overlooked. Years ago I published (The *Philadelphia Medical Times*, May 26, 1877) a paper giving the results of some investigations into the relation between onanism and urethral stricture, which led me to examine a large number of persons with healthy urethræ. In these examinations I found that without exception at a distance varying from 5½ to 7½ inches from the meatus the *bougie à boule* was arrested during its withdrawal from the bladder, and that the obstacle which was there encountered gave to the hand of the surgeon the characteristic sensation so familiar to those who have used this instrument in cases of stricture. It was evident that this condition could not be an abnormal one and its explanation was sought and I believe found in the anatomy of the curved portion of the urethra.

Any extended consideration of this would be inconsistent with the limits and purpose of this paper; but there are one or two points which seem to me worthy of special mention. Directly beneath the symphysis pubis the urethra perforates the posterior or visceral layer of the deep perineal fascia. A little in advance of this point is the anterior layer of the same fascia, continued round the under surface of the urethra, becoming lost upon the bulb and filling in the sub-pubic arch from in front. Between these two layers, which are often described as the triangular ligament, are found various vascular structures, important muscles, Cowper's glands, and the membranous urethra. It is said that the anterior layer exerts the larger share in stopping the progress of an instrument inward, owing to the fact that just in front of it is the freely movable and dilatable bulbous portion of the urethra, permitting considerable motion in the point of the sound, which is suddenly arrested at the commencement of the membranous urethra by this firm fibrous anterior layer. This is probably true; but it is capable of demonstration that the posterior layer, for analogous reasons, offers a similar opposition to the free withdrawal of a bulbous bougie. The prostatic urethra being at once more movable and more dilatable than the membranous portion, the bulb slips smoothly along it until the point is reached at which this layer of fascia closely embraces the posterior part of the membranous urethra and the outer surface of the prostate.

Here for obvious reasons it is arrested, and it is at this moment that the deceptive sensation which may be considered indicative of the existence of organic stricture is communicated to the hand.

A series of observations and dissections upon the cadaver confirmed me in this view, which was originally purely theoretical, and moreover eliminated the possibility of the resistance being due to a spasm of the compressor urethræ muscle which surrounds the canal at this point, arrest of the instrument occurring just as invariably after death as before.

The possible progress of the case described above, to which we may now return, had it not been interrupted by acute disease and death, can be easily stated. In consequence

of the imperfect emptying of the urinary tract, cystitis would sooner or later have resulted, and would probably have been regarded as the primary disease if the urethral coarctation had remained unrecognized. Pyelitis, or infiltration of urine, or both, would have followed, and would possibly have caused death by uræmic or pyæmic poisoning. It is of course admitted that the case is in many ways an unusual one. With the same amount of existing disease the subjective symptoms would ordinarily be much more marked, or the contraction giving rise to it would be of smaller calibre: actual ulceration is rare in these conditions, and an involvement of the urinary tract posterior to the bladder was hardly to be expected where there was so little obstacle to the stream of urine. The dilatation of the ureters in this case was probably due to the increased frequency of urination and the periodical obstruction thereby produced in the flow of urine into the bladder; at least, that seems to me a possible explanation. The facts remain, however, that the conditions which were found were simply exaggerations of the pathological processes which beyond a doubt result from any infringement upon the normal calibre of the urethra. I may select a few cases from my private practice to illustrate the same point.

Case I.—A man 30 years of age, a hotel-keeper in a neighboring city, applied to me some months ago on account of a troublesome gleet which had persisted for several years. It was of the most trifling character, came from the deep urethra, and was associated with the symptoms mentioned above: frequency of urination, dribbling, and slight hypogastric pain. He had, before coming to me, tried various methods of treatment, among them the use of steel sounds of a calibre of 26 and 28, which were as large as his meatus would admit and really seemed to distend the whole urethral canal. Thinking that the course had been insufficient in duration I recommended persistence in that method of treatment, ordering a 29 instrument which caused considerable pain at the end of the penis. He used this, with and without various injections and different methods of internal treatment, with no effect whatever. He became much discouraged and finally agreed to allow me to enlarge the meatus, a procedure which I had originally recommended but had not urged, as he was excessively nervous and as the aperture was of more than the average size. After doing this I ordered a No. 30 steel sound, intending gradually to increase the size of the instrument, but from the first week during which that size was employed his symptoms absolutely disappeared and he has never had any return.

I am of course aware that the result in this case may be attributed to the enlargement of the meatus. Ever since Mr. Furneaux Jordan called attention to the possible results of a congenitally small urinary meatus in males and females and recorded cases of urethritis, prostatitis, cystitis, and epididymitis due to this cause, it has been recognized as an occasional source of this and other genito-urinary diseases. Suprapubic pain, frequent micturition, lumbar pain, hæmaturia, preternatural sexual excitability are all in my own experience distinctly referable to contraction of the meatus and I must therefore admit that in the above case the enlargement of that opening may have been the active factor in producing a cure. As it would have naturally received a No. 28 sound with ease and a No. 29 with the use of a little force, it seems hardly likely however that its incision had much to do with the subsequent result.

Case II.—A gentleman aged 45 years, a widower, came to me on account of sexual disability characterized by imperfect erections and premature ejaculations. He had never had any venereal disease and had been happily married for many years, having a large family of healthy children. After the death of his wife there was a prolonged period of continence, at the end of which, under the influence of urgent sexual desire, he attempted intercourse on several occasions with entire want of success. He had been carefully and intelligently treated by his family physician, a man of large experience, and had used, as there was hyperæsthesia of the deep urethra, a steel sound No. 30, which he had introduced for himself twice a week for a period of some months. In addition to this, much judicious treatment had been employed. A physical examination gave absolutely negative results. The therapeutics of his case had been so comprehensive that I scarcely knew what to recommend, but, pending an examination of his urine, directed him to get a No. 31 sound and to insert it at the usual intervals, intending gradually to increase the size if the urethra would permit it. He disappeared for a few weeks from my office, at the end of which time he returned to report that he considered himself entirely cured, having for the first time for years had sexual connection. His cure has proved to be permanent.

Case III.—A gentleman aged 48 years, but remarkably youthful and vigorous for his age, came to me recently in great distress, giving the following history: He had been the subject of one or two gonorrhœal attacks early in life and had subsequently had a slight urethral contraction, for which he had been treated by gradual dilatation. He had been accustomed all his life to having regular and frequent sexual intercourse, but about a year previous to his visit to me had become engaged to a young and attractive woman for whom he had great respect, and had for that period been entirely continent. A month ago he told me he had been married, and to his dismay and mortification found that he was unable to perform the sexual act, erections being imperfect or fleeting, and ejaculation occurring prematurely. He had used his steel sound No. 28 without apparent benefit. No stricture or other abnormal condition of any kind was discoverable by the most careful examination, and, considering his years, he was apparently a model of physical health. I recommended the preliminary use of a No. 30, which went in with slight difficulty, and gave a cautious prognosis to prepare him for a somewhat extended course of treatment. To his and my own surprise and gratification, however, after a week or ten days the only distinct subjective symptom which he had had, a neuralgic pain in the right testicle, disappeared and shortly after he without difficulty established natural sexual relations with his wife.

Case IV.—A gentleman aged 30 years, a merchant of large interests whose business required constant visits to a neighboring city, applied to me for treatment for a condition of irritability which gave him great annoyance. He found that he was unable to retain his urine for more than two or three hours at the most, and on starting from his office for the water-closet, or more particularly on arising from his seat in a parlor-car to go to the urinal at the end of the car to empty his bladder, he would find great difficulty in controlling the desire, the urine sometimes escaping before he had time to unbutton his clothes. He had no other marked symptoms, but had been carefully examined by different practitioners for vesical calculus, stricture, prostatic disease, etc. His urine showed nothing abnormal. He had been instructed in the use of the steel sound and was then employing a No. 30, which certainly seemed to be a full size. I repeated the examination which had been made by my predecessors and found nothing to account for his trouble. As his visit to me came shortly after my experience with one of the cases recorded above, I advised him to get a No. 31 steel sound, although he felt quite sure that he would not be able to pass it, the 30 distending the urethra so completely. I thought it was worth the trial, however, although I was disposed to consider his case an example of the urethral erethism so frequently seen in railroad employés and to a less degree in commercial travelers, and resulting doubtless from spinal congestion consecutive to the continual jarring experienced in railroad journeyings. While I was yet undecided as to what further treatment I would recommend, he returned to report the almost complete disappearance of his symptoms following the first week's employment of the larger-sized instrument.

I have seen a number of similar but less striking examples of the same general truth, which it seems to me may fairly be expressed as follows: A difference in the size of urethral instruments employed for dilatation, so slight as to seem trifling and unimportant, may result in exceptional instances in a therapeutical effect far beyond what would be ordinarily anticipated; the practical conclusion from which is that, other means having failed or definite indications for other treatment being absent, we should never stop short of *full* dilatation in disturbances of the genito-urinary functions, the treatment being harmless in itself and sometimes so unexpectedly beneficial. While there is nothing new about these observations, it has yet seemed to me that even with genito-urinary specialists who are thoroughly familiar with the modern views in regard to strictures of large calibre, and certainly with general surgeons who do not always accept these views as a guide in practice, treatment is often defective on account of a failure to recognize that a slight difference, even that of one millimetre, in the circumference of the dilating instrument, may sometimes make considerable difference in the results obtained.

—Dr. Nathan R. Gorter, who accompanied Mr. Robert Garrett in his trip around the world, has sued him for $30,000 for professional services rendered.

—The effects of the "Scotch Oats Essence" Company, in New York, were sold out Dec. 7, by the Sheriff. Sixty-three gross of "Scotch Oats Essence" realized about four cents a bottle, the retail price being one dollar a bottle.

OPERATIVE PROCEDURE IN TRAUMATIC EPILEPSY.[1]

BY J. T. WILSON, M.D.,
SHERMAN, TEXAS.

Reflex epilepsy from traumatic injuries of the brain is not a rare trouble, and nearly every surgeon meets with one or more cases during his professional life. I believe it to be proportionately the most curable of epilepsies. It is a very important affection, and requires more study from the general practitioner than is usually given it. A great mistake is too frequently made by either not operating at all, or by waiting too long. In truth the tendency in these cases is too frequently to neglect them or prescribe only a palliative treatment. In this day of rapid surgical advance, when the hitherto sacred precincts of the cranium can be invaded with so much less hesitation than in former years, and with such comparative safety since the introduction of antiseptics, and with the brilliant record of brain surgery before us, where tumors and other pathological lesions are diagnosticated and removed with such splendid results as to astonish the world, no case of epilepsy caused by a depressed fracture should be permitted to progress without giving the unfortunate and wretched victim an opportunity to receive the benefits an operation might bring. Trephining does not aggravate the convulsions, and even if no benefit should result it does not leave the patient in a worse condition, when he has been properly prepared for the operation and it is carefully done under strict modern rules. Though hemiplegia exist, and its liability to remain is taught by the English surgeons, this should not deter us from operating and curing the fits if possible.

In my limited experience with this disease, I have found the convulsions in a majority of the cases extremely severe, sometimes quite frequent, and usually to a great extent one-sided: that is, the muscles of one side were nearly all involved in the spasm, though not in the same degree, and the muscles of the face and upper extremity of that side were in most cases more affected than those of the trunk and lower extremity. Antispasmodics generally have less control over them than over the attacks from other causes, and their controlling influence does not last so long. In a majority of the cases that I have seen, the general health was fairly good, the patients had morbid appetites and ate ravenously large quantities of food; and in all the cases coming under my observation, to the best of my recollection, the frontal, temporal and anterior region of the parietal bones sustained the injuries. General treatment, attention to the general health with tonics, antispasmodics and more especially the bromides would always lessen the severity, and to some extent the frequency, of the attacks for awhile; but the bromides largely given for any considerable length of time seemed to have a deleterious effect upon the health of this class of cases and also seemed to have a more unfavorable influence upon the mental state, inducing early dementia.

Persons predisposed to epilepsy, or who are very nervous and excitable, or very susceptible to nervous shocks, are more liable to epilepsy from fracture or other injuries of the skull and scalp than those who are differently constituted. In one patient a slight depression will produce it, in another a deep one will not, though both occur in the same locality; and in these nervous cases an operation is especially likely to do good; but in all it is of paramount importance to do the operation thoroughly.

In this connection I will report two cases, illustrative of the object I have in view, which taught me an important lesson in regard to operating upon the skull and brain for epilepsy caused by an injury; and the lessons there learned served me a useful purpose in other cases.

Case I.—J. H. O., American, male, æt. 40, married, occupation farmer. No reliable family history could be obtained except that he had always been very nervous and excitable. General health fair, though the patient was not robust, and was of very nervous temperament. He was affected with chronic melancholia, and had attempted suicide by cutting through his skull with the sharp corner of an axe, the wound being through the coronal suture, involving the frontal and parietal bones, about half an inch above the temporal bone of the right side. Not succeeding by this means, he made another attempt a few days later by driving a "number six" nail through the opening in the skull made with the axe. This nail was driven for more than an inch into the cerebral tissue. A physician saw him soon after and extracted it, dressing the wound in the ordinary, old-fashioned way. Some suppuration supervened, and the wound closed by granulation. Paralysis

[1] Read at the meeting of the Southern Surgical and Gynecological Association, Birmingham, Ala., Dec., 1888.

of left side gradually came on, and in six weeks was almost complete. A few weeks after the closure of the wound the patient was attacked with epileptic convulsions, and they recurred at intervals of from one to three weeks for several months. As time passed they grew more frequent and severe. Bromides in full doses seemed for awhile to lessen the severity but not the frequency of the attacks, and finally seemed to lose all effect over them; while after the use of them for several months the patient's digestion began to suffer, and symptoms of beginning dementia were strongly marked. Strange to say, the paralysis slowly improved sufficiently to enable him to walk about with the assistance of a cane. At the end of nine months from the reception of the injury the administration of bromides was discontinued, and the patient was put upon a tonic regimen for about two weeks. At the end of this time he was anæsthetized, the scalp was shaved, and a crucial incision was made over the old cicatrix. As the scalp was dissected up and drawn back, a small oblong depression of the skull was found, and in its centre a small opening leading down to the dura mater, the bone having sloughed away. The trephine was applied and two buttons of bone were removed, embracing the entire length of the depression. A thick cicatrix of the dura mater was observed; but as it looked healthy, and as the epilepsy was thought to be caused by the depressed bone, the cicatricial tissue was not interfered with, and after all the depressed bone had been removed the wound was closed by the ordinary method. It healed readily under cold water dressings. The patient now improved rapidly, and for three months had no convulsion. His general health improved, and the paralysis improved so much that he could walk comparatively well with the assistance of a cane, and go wherever he desired. His mental condition also mended considerably, and the man was more cheerful than he had been for months, so that it was thought that his recovery would in a short time be complete.

After the lapse of three months, however, he began to get somewhat nervous and morose; his appetite decreased and his paralysis increased. His melancholia began to be markedly observed. He was now restless, though not inclined to walk much, was troubled with insomnia and at times complained of quite severe pain in his head. A marked change in his general condition was easily observed. This change came on rapidly; and one morning after waking from sleep he was attacked with a very severe convulsion which lasted nearly two hours, and from which he never rallied, but sank and died in three or four hours. The autopsy revealed a very much contracted calibre of the trephine wound, it having filled up with new tissue. The old cicatrix of the membranes was hard and firm, bulging a little and adherent to the skull around the wound. When it was incised, an abscess of the brain was revealed, in which was found a small spiculum of bone about half an inch in length. The brain tissue was softened and slightly discolored for perhaps a sixth of an inch around, extending into the cerebral tissue from the abscess cavity.

If when this patient was trephined the cicatrix in the membrane had been cut away, the part explored, the piece of bone removed and the diseased brain scraped away, it is highly probable that his epilepsy and perhaps his paralysis might have been cured and his life prolonged.

Case II.—T. M.; American; male; æt. 24; farmer; fell from a tree a distance of over twenty feet, striking his head upon a hard substance and sustaining a fracture of the skull involving the frontal bone of the left side near its junction with the parietal. According to the history obtained, he was said to have remained insensible for several hours and to have been confined to his bed for nearly three weeks. He gradually recovered, and in the fifth week after the accident, and after a day's labor of unusual severity, was attacked with epilepsy followed by another seizure the next day. Another occurred after an interval of two weeks, and similar seizures recurred at irregular intervals for fifteen months, the attacks growing more frequent and severe. Any unusual mental or physical exertion brought them on. Very little benefit was obtained from internal treatment; his digestion was much disturbed by large doses of bromides; he had a morbid appetite; his intellect was dulled, and his case presented a gloomy prospect.

After about ten days' preparation he was trephined, two buttons of bone were removed, and a small piece of the internal table lying loose was taken away. The wound was closed, and it healed without trouble. He was confined to his bed for ten days, and in fifteen days after the operation left his room. He seemed to be doing well until twenty-one days after the operation, when he had a mild epileptic attack, and these

attacks were repeated with variable frequency and severity for four months, when it was determined again to resort to operative procedure. A V-shaped incision was made; the flap was turned back, and two buttons of bone were removed from the sides of the old wound. A tense cicatrix of the dura mater was discovered, and it was carefully removed entire. The brain beneath presented no perceptible pathological lesion. The wound was washed with warm carbolized water, the scalp was dissected up for nearly an inch around the wound, and the edges were brought together with silk suture and closed up. The patient recovered without an untoward symptom. He had five or six mild spasms in the following three months, when they ceased altogether, and after five years—when heard from a few months ago—he had had no further trouble, but remained well and able to cultivate his farm.

These operations were not done under strict antiseptic rules, as the practice had not come into such general use as at the present day; but in the second case warm carbolized water was used.

This experience taught me that in all cases of trephining, when the bone is removed, the part of the brain and membranes exposed should be carefully examined, and that if a cicatrix exists it should be removed, as also that any foreign substance or pathological lesion of the brain should be cut or scraped away under thorough antiseptic precautions. If hemorrhage occurs, and continues after washing with hot water, the cavity can be very carefully and lightly packed with antiseptic wool, care being taken that the packing be not too tight, as the pressure thus made might result in mischief; and as soon as the hemorrhage has been controlled the packing should be removed.

It is not the pressure of the bone in every instance that causes the reflex disturbance; for the brain will sometimes become accustomed to this pressure if not too great, and its function may go on as before, after recovering from the shock of the accident. But if the membranes should have been lacerated at the time or sustained some other injury, followed by a circumscribed meningitis, a cicatrix will form, possibly adhesions and some contraction will take place; the cortical substance will be irritated, and from this cause convulsions are liable to ensue. Or, circumscribed inflammation may extend to the brain, and an abscess result; or a spiculum of bone may be driven into the cerebrum, and its presence may excite the disease. Therefore these sources of irritation should always be looked for and, if found, removed. Mr. Victor Horsley thinks that after a button is removed, if it is noticed that the dura mater bulges through the opening, it is an indication of the existence of pathological intercranial tension.

I believe that, in all cases of epilepsy caused by depression from an accident, a contracted cicatrix of the scalp, or a sensitive spot in the head (as in a case that came under my observation some years ago, in which pressure upon a sensitive spot would produce convulsions), trephining is not only justifiable but is demanded, and should be done without hesitation. If the bone is thickened, Prof. Briggs's teaching[1] is correct: remove it; trephine a second and a third time if need be, taking away all the diseased bone; or, even though it be not diseased, if there is much unnatural thickness, remove it, and if any pathological condition of the membranes or of the cerebrum be found, it should without hesitation be carefully cut away, leaving only healthy tissue, especially as regards the cortical substance; and no tense thick cicatrix of the membranes should be allowed to remain. Even thick, sensitive cicatrices of the scalp should, in my opinion, be removed, if there be the slightest suspicion that the epilepsy is caused by the traumatism.

After these operations the healing is materially assisted and subsequent danger is lessened by dissecting up the scalp for a few lines around the wound in the skull before it is brought together, in order not to have too much tension by cicatricial contraction. The wound should be carefully dressed according to the antiseptic method, and watched, every source of supposed irritation being removed; and if possible it should be made to heal by first intention, in order to prevent the formation of an extensive scar. The general health of the patient should be looked after; his excretive functions should be kept active and his nervous system tranquilized. The patient should be kept quiet and cheerful, away from all sources of excitement and from everything that would in any way affect his general health, for several weeks after recovery seems complete. In my judgment, success depends very much upon careful and judicious after-treatment.

In long-standing cases improvement in the convulsions does not always begin at

[1] *International Encyclopædia of Surgery.*

once; sometimes several months elapse before the improvement is marked and the habit gradually broken up; for there is a good deal in the habit the brain sometimes gets into with regard to these convulsions. Many neurologists now think that "idiopathic epilepsy has its origin in the cortex of the cerebrum, and from a surgical standpoint it is therefore not difficult to understand that any chronic endo-cranial lesion which affects this part of the brain can produce epilepsy." Dr. Senn,[1] of Milwaukee, in his investigations recognizes as causes of reflex epilepsy affections or wounds of the peripheral nerves, which indirectly affect the cortex of the brain, as well as lesions of the cortex itself.

It sometimes occurs that in trephining the skull for injuries or disease the surgeon is not careful enough in his exploration of the wound, and fails to remove splinters of bone or any other foreign substance which is liable to cause an inflammatory condition, and may produce epilepsy among other troubles.

Is it too much to hope that surgery may yet come to the aid of many epileptics who are otherwise considered incurable and doomed to a life of untold misery, whether their trouble is of traumatic origin or not?

EPITHELIAL CANCER OF THE THROAT AND NOSE; RECOVERY.

BY E. W. EDWARDS, M.D.,
CHICAGO, ILL.

About the first of May, 1887, I was consulted by Charles H. Crane, aged fifty-two years, a native of New York, married, the father of two children, one boy and one girl. The boy is compelled to live in Colorado to escape consumption, with which he is strongly threatened. The girl, about fifteen years old, is healthy. Mr. C.'s early years were spent on his father's farm as an assistant. At nineteen he commenced life for himself and settled in Illinois. He was robust but subject to autumnal attacks of bilious intermittent fever which was endemic in this State at that time. He was also subject to rheumatic troubles from which he suffered severely at times; but still he enjoyed good general health when free from these two maladies. He has for years been connected with the In-freight Department of the Pittsburg, Fort Wayne & Chicago R. R. in this city.

An examination of his case showed that he was suffering from epithelial cancer of the throat and nose. At the extremity of the nose there was pendent an excrescent morbid growth about three-fourths of an inch long, which resembled a rusty strawberry, and was more connected with the left ala. The nose was discolored above the junction of the cartilage of the septum with the nasal bones; the whole nose was swollen and congested, the capillaries and superficial blood-vessels being visible to the naked eye.

The face was swollen above the point of discoloration and was of a putty color and œdematous, showing upon pressure the characteristic dropsical infiltration. The nasal mucous membrane was diseased to the posterior nares and as far down as the œsophagus. The pharynx was highly ulcerated, and thickened to such an extent as seriously to interfere with deglutition, to the exclusion of all solid food. The liquid food had to be concentrated so as to increase the nourishing qualities in order to sustain life, until the improvement in the condition of his throat enabled him to take solid food.

My first effort was to get rid of the warty excrescence of the nose. To this end I applied a saturated solution of chloride of zinc, in a circumscribed ring at the base of the wart, as near as possible to where I thought the healthy nose should be. Then I painted the excrescence with liquor ferri sub-sulph. The nostrils were treated with a five per cent. solution of carbolic acid, with a wire probang armed with the finest commercial cotton. This was used because absorbent cotton becomes too rough and harsh when saturated with any of the remedies used in the treatment of cases of this nature, and especially when the probang is armed with the brush of cotton and has to be passed down through the nasal passages to the posterior nares. Then a whale-bone probang, suitably curved and armed, was passed up behind the velum, sweeping every part of the mucous membrane in the region of the posterior nares and the upper part of the pharynx. The cotton wrapping was then removed from the probang and a new covering of cotton was put on, saturated with the iron-solution and applied to the part as before. A new brush must be used for every application and saturated with the solution of iron, or a solution of chromic acid—thirty grains to the ounce of distilled

[1] *Annual Universal Medical Sciences*, Vol. II, 1888.

water; thus alternating with chromic acid and iron twice a day. I always preceded the other treatment with the solution of carbolic acid, for two reasons: first, to cleanse and disinfect; and second, to produce a local anæsthetic effect which should mitigate the harshness of the other treatment. An ointment composed of equal parts of extract of belladonna and ointment of iodine, spread upon a piece of chamois skin large enough to cover the nose, was kept constantly applied over the nose. The object of the belladonna in the ointment was to remove the pain and to relax the infiltrated and thickened cuticle, so as to render the iodine ointment readily and quickly absorbable. The reason for the use of this compound ointment on an unbroken surface is obvious to an observer.

I always aimed to allow plenty of time for each of the applications to the nose and throat to have its local alterative effect upon the diseased membrane; and this required more than an hour. The treatment is not pleasant, especially the solution of iron. When the iron was applied to this patient's throat, he would be seized with the most terrible nausea and retching; but a little whiskey relieved this more promptly than anything else I ever tried. The other local remedies were not so severe nor did they taste very unpleasant; but when the subsulphate of iron was applied to the diseased part of the pharynx, its effect was felt severely.

As a finish to the other local treatment, I applied by insufflation iodoform mixed with sufficient boric acid to render the powder divisible to the point proper for insufflation.

There was one thing in the history of this case worthy of mentioning, from both a physiological and pathological standpoint. The man was one of a family of nine children, six of dark and three of light or blonde complexion. The children with light complexion were troubled with inveterate eczema, which did not manifest itself until those subject to it arrived at the age of maturity. In the case of my patient, it is worthy of note that when the nose and throat gave evidence of the greatest degree of malignancy, the eczema disappeared from the skin. And as soon as the throat and nose showed a disposition to yield to treatment, the skin disease commenced to re-establish itself upon the surface of his body. Now, does this fact indicate that the skin disease and the cancer were two manifestations of the same hereditary cachexia? That there existed a strumous or scrofulous diathesis is evident, and it must have dated back for generations. The mother of the patient was troubled with a skin disease, though no cancer was ever known to exist in the family. May not the cancer in the case have been only a culmination of the scrofulous taint?

The constitutional treatment prescribed consisted of a combination of tonics and alteratives which was not only to assist in effecting a cure, but also to obviate, if possible, the recurrence of the disease in some other part of the patient's body, and was as follows:

℞ Syr. ferri iodidi . . . . . f℥ij
Liq. arsenicalis . . . . . f℥iv
Ext. conii fld.,
Tinct. nucis vom. . . . . āā f℥iij
M. Sig. Twenty drops three times a day, increasing one drop every four days.

Of course, the constitutional effect was watched as a guide; but it is astonishing to see what large doses of these powerful drugs a patient laboring under this diathesis will bear, when they are not increased too precipitately.

As a year has elapsed since his cure was effected, and as Mr. C. is enjoying excellent health, I feel safe in reporting this case for the encouragement of the profession.

Several years ago I treated a case of cancer of the throat, and, although the woman got well, I did not dare report it, as the patient was an obscure one, and her surroundings not such as would protect my unsupported statement of a cure from cavil. But in the case just described, the intelligence of the patient, and the fact that the case was seen by a number of other physicians during the treatment and since his recovery, make it proper to report it as a cure.

—The *Lancet*, Nov. 24, 1888, says that the Professorship of Medicine in the University at Vienna, made vacant by the death of Professor von Bamberger is, it is said, to be given to Professor Schrötter, whose name is best known in connection with laryngology. Professor Schrötter is, moreover, a general physician of great ability. His appointment is likely to be hailed with pleasure by English and American students, as he not only speaks English, but lectures in German in so simple a manner and with such distinctness of utterance that it is much more easy for a foreigner to understand him than many of the other teachers in Vienna. Meantime, the lectures at the late Professor Bamberger's clinique are being delivered by Dr. Neusser.

FOREIGN BODY IN PERITONEAL CAVITY.

BY J. L. CRAWFORD, M.D.,
PRESIDENT WESTMORELAND CO. MEDICAL SOCIETY, GREENSBURG, PA.

On August 18, 1888, Mrs. K. consulted me at my office, giving the following history: Her age was twenty-eight years, and she was married six years ago, and had been a widow for two years. On July 16, having passed her regular time for menstruation, she concluded that she was pregnant, and at the suggestion of a friend, in order to bring the matters right, she resorted to the use of a lead-pencil, passing it as she thought into the womb. Hemorrhage came on in a short time afterward, and an hour later when she attempted to remove the pencil she could not find it; but felt confident that it had not come away. She then sent for Dr. McDonald, who resided near by. He examined her carefully, but failed to find the pencil and as there was no pain nor appearance of injury or laceration, he discredited her story; believing that if she had used a pencil at all, it had come away without her knowing it.

The woman continued to perform her household duties until August 18, almost five weeks, without any pain or other symptom of trouble. On that day a very tender spot appeared on her abdomen, at a point three inches below and two inches to the right of the navel. Movement became painful, and in this condition she came to my office, reciting the history given above.

I had but little faith in her story, as I thought it was impossible that a foreign body such as a lead-pencil could remain in the abdominal cavity for so long a time without exciting acute peritonitis; but I proceeded to make a careful examination and was satisfied that I felt the pencil in the abdominal cavity just where the soreness and tenderness had developed. I sent for Dr. R. B. Hammer, who came to my office and, after a careful examination, concurred in my opinion. This was late on Saturday evening. As the woman was not able to arrange for operation on Sunday, it was postponed until Monday morning, August 20.

By this time peritonitis had fully developed, and she had suffered intense pain during Sunday and Sunday night; her abdomen was swollen and tympanitic; and her pulse was one hundred, and wiry.

She was anæsthetized, and, with strict antiseptic precautions in every particular, assisted by Drs. R. B. Hammer and C. C. Porter, I made an incision through the belly-wall about eight inches long in the median line, commencing near the navel. The pencil was soon found lying transversely, one end near the navel and the other penetrating the ascending colon. The edges of the wound in the colon were freshened and closed by three fine cat-gut sutures.

The intestines and peritoneum were in a highly congested condition. The abdominal wound was closed first by interrupted cat-gut sutures passed through the parts on each side, then a continuous suture was used and the wound perfectly closed except a very small angle at the lower part; no drainage tube was used, the usual antiseptic dressings were applied.

The patient rallied quickly and well from the operation. The after-treatment was conducted by Drs. McDonald, Porter, and Hammer. The patient was kept well under the influence of morphine for several days. She vomited considerably for two days after the operation. Her temperature at no time exceeded 100°, nor did her pulse go above 90. The wound healed by first intention throughout its whole extent. Three weeks from the day I operated, she came on the train and walked four squares to my office; and at the present time she has fully recovered, and for several weeks has been doing her usual work, washing, ironing, etc.

The room in which the operation was performed was a small, low, dingy place. The next day after the operation, the room was flooded during the great rain-storm of August 21, so that in her fright the patient jumped out of bed and was then carried upstairs, by a narrow crooked stairway; but, notwithstanding all the unfavorable surroundings, she made good and rapid recovery.

The part she penetrated in passing the pencil up must be a matter of conjecture. Neither the womb nor any part of the vagina showed signs of laceration at the time I examined her. The pencil was an ordinary lead-pencil, six and three-fourths inches long, with a smooth brass cap on the end which she says she passed first. The lead and glue were softened. The pencil was removed intact, yet it fell apart when exposed to the air.

The points of peculiar interest in this case are just how and through what parts it penetrated in passing, and the tolerance by the peritoneum of the foreign body for so long a period.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, November 7, 1888.

The President, J. Solis-Cohen, M.D., in the Chair.

Dr. J. M. Baldy read a paper on the

Treatment of Peritonitis,

in which he said that his views are considered somewhat radical from a medical point of view; but he thinks they are views toward which surgeons are gradually drawing nearer and nearer, and of which actual experience is daily demonstrating the value.

Peritonitis arises from a great variety of pathological conditions, and in dealing with it the origin of the inflammation must always be taken into consideration. The plan of immediately putting every patient with this disease on the opium treatment has ceased to prevail. No one would think of pursuing such a course in a peritonitis following rupture of an abscess, for instance, provided an abscess was known to have ruptured; nor in the case of a penetrating wound of any of the hollow viscera, with extravasation of the contents into the peritoneal cavity. The first thing to be determined when called to a patient suffering with peritonitis is the cause of the trouble. This is not by any means an easy thing to do. A patient may present all the symptoms of peritonitis, but on close examination prove to have an inguinal hernia. The temptation here is immediately to set this down as the cause, and proceed accordingly, especially if the hernial mass is tender, and presents other symptoms of excitation, where before it had been quiescent. In such a case one may readily be misled, and the real cause found to be something else. Again, although the books lay down most beautiful rules for diagnosticating the different varieties of intestinal obstruction, it is often impossible to say more than that there is probably mechanical obstruction of some kind or other, somewhere in the abdomen; but even then one cannot be sure but that the obstruction is caused by the peritonitis, and not the peritonitis by the obstruction. Dr. Baldy has seen peritonitis in cases in which, on examination, it was not at all certain that the pelvic contents were at fault; and yet an operation showed that they were. He could go on indefinitely multiplying instances of mistakes of this kind, and mistakes which are perfectly justifiable in the majority of cases. It is simply impossible in a large number of instances to do more than guess at the real cause. But although the cause cannot always be detected from a mere examination of a patient, it does not follow by any means that the disease has arisen idiopathically. Dr. Baldy does not, however, deny the possibility of its existence.

On the other hand, cases of peritonitis are constantly occurring in which the diagnosis is comparatively easy, and the indications for treatment plain; while the exact condition of affairs remains in doubt, the best men may hesitate, and often this hesitation is responsible for the unfortunate ending. Given a correct diagnosis, however, there should be no hesitation as to the course to pursue.

The author unhesitatingly condemns the use of opium in any of its forms. He says: "I think the use of this form of drug, in these diseases, tends rather to increase the trouble than to diminish it; at any rate, if it does not do damage *per se*, it certainly puts the parts in an excellent condition to continue on in the course in which they have started, and blinds us to the damage being done. In a paper read before the Obstetrical Society last November, on 'The Use of Salines in Peritonitis after Laparotomy,' I dealt with the use of this drug quite extensively, and my convictions then stated have been constantly confirmed and strengthened, not only in peritonitis following operation, but in peritonitis from all causes."

Opium, he says, also almost invariably causes tympanites, with all the accompanying dangers of over-distention, and it has caused death from cardiac paralysis. Further, the drug lures the physician into a false sense of security, and benumbs all his desires to make any further effort in the patient's behalf. The pain and tenderness being relieved, and the sufferer comparatively comfortable, he stands by and waits, the waiting as often leading to the coffin as not. After having stupefied and benumbed the patient, a consultant is perchance called in to the case, only to find his hands tied, by having all the symptoms masked, and with no possible way of knowing what progress the disease is making except by a surgical procedure, and this, in view of the fact that the patient *seems* better, he dares not propose.

In great contrast to this picture stands

the results of the use of salines. Here the bowels are put into active peristaltic action; this motion tends to prevent the formation of adhesions and bands; the peritoneal cavity is drained of the products of inflammation; the inflamed surfaces are relieved of all engorgement by a thorough depletion of the vessels in the intestinal walls; the inflammation is most effectually stopped; the pulse and temperature almost immediately improve, and the pain is relieved as quickly as by the use of opium. This, theoretically, says Dr. Baldy, may seem strange, but he nevertheless declares it to be a clinical fact.

While writing this paper the author says he was called to a woman sixty years of age, with symptoms of acute peritonitis, but the cause of the attack could not be detected. Salines were administered, and in much less than fifteen hours the belly-walls were shrunken and flabby, permitting of free manipulation, with hardly any evidence of pain; vomiting had ceased; pulse and temperature were both in good condition, and, in fact, all the symptoms were rapidly disappearing. She had passed a most comfortable night, sleeping almost the whole of it. In twenty-four hours more he had discharged the patient, notwithstanding the fact that the case had appeared so bad when first seen, that he had notified his nurse to be ready for a possible operation the next day. This same result, he asserts, has followed this treatment so often and so constantly in his hands that he has come to look for it with certainty. Of course, if a strangulated hernia is suspected, or pus in the peritoneal cavity, or obstruction of the bowels by an organic lesion at any point, he would not think of resorting to purgation, but would immediately turn to surgical resources.

The sources of a peritoneal inflammation are so numerous, it would be useless to attempt farther to enumerate them; but he thinks the general rule might be safely laid down, that where it can be demonstrated that the disease is caused by an organic lesion, abdominal section is indicated; and that, in addition, those cases which refuse to yield speedily to purgative treatment should be immediately dealt with in the same manner. When a pus-sac is known to be at the bottom of the trouble, or an appendicitis is in existence, it is folly to employ drugs of any kind; and where drugs are used and relief does not quickly follow, whether the cause is known or not, it is equally unwise to delay longer. The source of the disease once removed, the peritonitis will rapidly disappear. Cases reported in the journals are constantly demonstrating the worthlessness of all medical interference, and are steadily pointing to the fact that peritonitis is preëminently a surgical disease, and should not be intrusted in the hands of a purely medical man, but should be always and at once turned over to the surgeon. An abdomen containing pus, either encysted or free in the cavity, whether produced by puerperal disease or any other, demands opening and removal of that pus. If there is not active peritonitis present, the person afflicted is liable at any minute to be so attacked. This fact does not seem to be sufficiently understood, and physicians are continually treating pelvic abscess with local applications, electricity, etc., sometimes suspecting the true condition, at others mistaking it for some other condition, such as tubal pregnancy, for instance. Where an intestinal obstruction, an appendicitis, an inflamed tubal condition, a penetrating wound of any of the viscera, a tumor, or any one of a dozen other troubles is found, it should be dealt with according to our present surgical light. In such cases as these, peritonitis is not a disease, but merely a symptom, and when the original cause is removed the trouble subsides at once. Often the mere opening of the abdomen, together with irrigation and drainage, is sufficient. This seems especially to be true of those cases of tubercular peritonitis, so many of which have lately been springing up, and to which attention was called by the author in his paper on "Exploratory Laparotomy" last spring. He then showed that six deaths from various causes had taken place out of thirty-six cases collected in Germany, and only one death out of seventeen cases which he had collected in this country. This death was due, not to the operation itself, but to defects in the details of the operation. In all these cases irrigation or drainage, or both, followed the operation, and seemed all that was needed to effect a permanent cure.

In conclusion, Dr. Baldy says that when called to attend a patient suffering with peritonitis, we should first determine the cause, and if it is found to be an organic one, the immediate use of the knife, followed by irrigation and drainage, is the only proper method of procedure.

If the cause is found to be functional, the use of purgatives, followed, if necessary, by enemata, is indicated; and these failing

to relieve quickly, surgical measures should soon follow.

If the case is of doubtful character, he would be inclined first to try the purgatives, and stand ready to interfere with the knife at a moment's notice.

He admits, however, that it is impossible to lay down any absolute general rules for the treatment of every case, as each one must be a study by itself.

Dr. Arthur V. Meigs read a paper on

The Treatment of Peritonitis.

The question how to treat peritonitis is one of the greatest importance, and upon the decision eventually reached will in the future depend the lives of many patients. Should the leaders of our profession decide that the administration of saline purges is the best treatment, and this be for a few years taught in the schools, the ordinary practitioner will soon acquiesce. If such a consummation is to be deplored, now is the time for us who are of the contrary way of thinking, to protest.

To me it seems clear that before any conclusion can be reached, it must first be acknowledged that peritonitis, as ordinarily seen, diagnosticated, and treated by physicians, is so different from the lesion or disease which has been successfully dealt with by surgeons by the administration of saline purges, that it must be recognized that, from the standpoint of therapeutics, the two questions are as far apart as though there were two widely differing diseases.

As a therapeutic measure, no one disputes the wisdom, under some circumstances, of making an attempt to abort an inflammation; and yet it is equally well known that such an attempt, when made after the inflammation has progressed so far that to abort it has become impossible, must not only fail, but equally certainly will be productive of positive harm. It is a common rule of treatment, and one that holds good in the great majority of instances, that an irritated, sore, or inflamed part is to be put as nearly as possible at rest, and that whatever increases the pain suffered is likely to be injurious. Why shall we make an exception to this rule in all cases of peritonitis by giving salines, which throw the bowels into a state of great activity, and increase the pain, at the same time denying the patient opium, which equally certainly relieves?

I have been and am an advocate of the use of opium in all cases of peritonitis as seen by physicians, but at the same time I have never denied my patients the use of laxative medicine, and it is, I am sure, by the judicious administration, according to the special needs of each particular case, of the two seemingly diametrically opposed drugs that the best results will be attained. The reason, probably, that the use of opium in the disease is being decried is that it has been abused. It should not be given to the point of narcosis, nor should it be expected that in cases of severe peritonitis the pain will be abolished. Measurable relief only should be looked for, with alleviation of the terrible colicky pains so characteristic of the disease in its full development. I have never been a believer in the treatment by the use of anodynes exclusively, and think it absurd to talk—as I have heard—of purging the patient by the use of opium and belladonna. If we had six months in which to work, and could first establish the opium habit in the patient, we might, perhaps, encourage diarrhœa, or at least not interfere with it, by the administration of opium. In a disease, however, which lasts usually but a few weeks at the very outside, such an expectation can end but in disappointment. The treatment that will give the best results, according to my view, is the following: in all cases in which no physical obstruction can be diagnosticated, for which operation must be at once recommended—and this should include doubtful cases in which operation may subsequently become necessary—there should be prescribed liquid diet, small quantities every two hours, and every two hours a quarter of a grain of opium, and one-twelfth of a grain of extract of belladonna. To this may be added, if it should seem advisable on account of pain, the administration twice, or at the outside, four times in twenty-four hours, of a one-grain powdered opium suppository. At the same time injections of warm water, with or without soap, should be given once to three or four times daily. If flatus is passed, the case continues to be a very hopeful one. This course should be rigidly adhered to for from twenty-four hours to five days, or possibly longer, when the time will have arrived at which it becomes necessary to consider the propriety of using some sort of aperient.

Purgatives are given in peritonitis for two distinct purposes: first, to increase the peristalsis, and thus overcome obstruction; and, second, to induce large watery movements, for the purpose of directly depleting the abdominal, and especially the intestinal, blood-vessels. After operations, inflammation in greater or less degree is so common,

and we are so well aware that it is liable to occur, as to be always prepared to meet it. This being the case, it may be met in its very incipiency, and if inflammation can ever be aborted, it is under such circumstances. The explanation of the success, therefore, of surgeons in treating peritonitis with large doses of saline purgatives would seem an easy one, for they deal with a stage of the disease which never comes under the management of physicians, as people in the early stages of the disease do not seek advice; and, besides, if they did, the differential diagnosis between idiopathic peritonitis in its earliest stage and enteritis or mere intestinal irritation would be an impossible one. No one, I think, should deny surgeons the credit their courage deserves for having instituted this revolutionary method of treatment, for, measured by our old standards, it is revolutionary; but at the same time we must not err upon the other side, and with undue haste conclude that the method is applicable to all cases. I have long been of the opinion that the old surgical practice of shutting up the bowels for a week, with opium, after an operation for hemorrhoids, is a bad method.

Having, then, quieted our patient somewhat during the first few days of attendance, with injections and liquid food, and belladonna and opium, and at the same time been very careful not to induce narcosis, or in the least to depress the respiratory forces, for, if we do, the remedy will be worse than the original disease: we must, as already said, consider the propriety of getting the bowels moved. The decision in regard to the precise moment at which this attempt is to be made is, in my opinion, one of the most delicate questions that can arise in therapeutics, and gives to each of us, when we meet it, an opportunity to show a real genius for the treatment of disease. The medicine, however, which shall be given is very easy to decide upon—here there is no inflammation in its early stage, and, therefore, there can be no question of aborting it. Salines could only act upon the bowels like other drugs, relieving tension, if you like, by abstracting water directly from the intestinal blood-vessels; but, so far as the mere moving of the bowels is concerned, they are by no means so effective, or, as the laity call it, "searching," in their action as some of the vegetable purgatives. Anyone who has been called upon to treat cases of fecal accumulation (a paper upon this subject was published some years ago by the speaker, in the *Transactions of the College of Physicians of Philadelphia*) will have learned how useless and ineffective are salines if the bowels are very sluggish, while small and repeated doses of vegetable purgatives are perfectly satisfactory and certain in their effects. In such cases salines, and even castor oil, will induce large watery stools, but no fecal matter is brought away, and it seems as though the fluid material had come from below the accumulated feces, or had come by, and the patient is no better off than before, though probably he will have suffered much pain. No better combination can be given than a pill consisting of a twelfth of a grain of extract of belladonna, a quarter of a grain of extract of nux vomica, a quarter or an eighth of powdered aloes, and a half or one grain of rhubarb. This should be given at first once or twice in twenty-four hours, and, if violent pain be set up—which, however, seldom happens—it should be stopped, and the opium and belladonna every two hours used again for a day or two, when the attempt with the aperient may again be made. After a day or two the pill may often be given every four hours, and I have often seen the obstruction give way under this treatment, and the patient entirely recover.

It would be most unfortunate, it seems to me, for the science of medicine, and still more so for those who in the future are to suffer with peritonitis, if the treatment of the disease with sedatives should be entirely abandoned, as has been recommended here this evening. Let us look at the question reasonably and without prejudice, and in the future assign to one class of patients operation by a competent surgeon, and saline purgatives afterward, if those skilled from a study of the subject in that particular direction judge that to be the proper course; and to the other, a reasonable use of anodynes and injections, with moderate doses of vegetable laxatives when the time comes for their administration. Because, in the past, the sedative method of treatment has been abused, and patients have been hurried out of the world by the unwise management of incompetent physicians who have narcotized them, is no reason why we should cast aside what is good in the method, any more than it would be wise for us now to assume that, because the administration of saline purges is advisable in the surgical treatment of some cases, it is therefore to be looked upon as a panacea in the disease, and the treatment to be recommended in all cases.

For my own part, I am a firm believer that the disease may arise idiopathically, and, when I say this, I mean from an attack of enteritis or violent indigestion, or from chilling of the body, just as I believe pleurisy may arise; and, in such cases, it is reasonable to suppose that the inflammation very soon becomes more or less generalized, though, of course, it must have had its origin at some point. Such cases as these, if it be conceded that they ever arise, are not amenable to surgical treatment, for there is no point of special obstruction, and operation could not effect any good, unless by merely cleansing.

In conclusion, I cannot, perhaps, better emphasize the correctness of the statement that the treatment by sedatives should not be abandoned in all cases of peritonitis, than by calling your attention to the fact that in many cases in the past, and the same thing is certain to occur again in the future, post-mortem examination has demonstrated that the disease was so extensive or of such a nature as to be necessarily incurable. Under such circumstances, I think, no one will dispute that the province of the physician is to do what he can to soothe pain, and make the last days and hours of the patient as endurable as circumstances permit, and no other one drug will conduce so much toward this end as opium.

Dr. J. H. Musser, in opening the discussion, said that he believes cases of idiopathic or so-called functional (?) peritonitis must be very rare, for in the course of a tolerably large experience he has not met with any. A successful treatment of all cases must depend, in the first place, upon the recognition of the many antecedent pathological conditions that may be considered as causal. A large majority of the cases which he has seen recovered without resorting to surgical measures. In these instances a similar plan of treatment to that suggested by Dr. Meigs was to a certain extent carried out, notwithstanding the fact that a local or a focal origin of peritonitis could always be determined. The plan of treatment which he has carried out in most of the cases has been rather simple, beginning in the first place with local depletion either with blister or with leeches —not fearing the depressing effects of local depletion, but rather encouraging further bleeding by following the depletion with poultices, and possibly by general stimulating applications, such as turpentine. He endeavors to open the bowels as early as possible, and uses principally, if vomiting is present or not, calomel in doses of one-twelfth, one-eighth, or one-fourth of a grain every hour or half-hour, until the desired effect is produced. He is not disturbed if, in addition to the purgative effect, he gets a constitutional effect of the drug also, for its antiphlogistic effects in peritonitis are undoubted. With regard to opium, he uses it simply to relieve pain, and hence in the smallest doses possible. He prefers the hypodermic injection of morphia, of which sometimes an eighth or a sixteenth of a grain, twice daily, will suffice. In addition to the anodyne effects of the drug, its stimulating effect is of service; and after the mercurial has acted on the bowels, he combines the extract of opium with the drug, giving the opium more and the mercury less frequently. Usually he uses atropia with the morphia, and in this way counteracts the depressing effects of the opiate. Stimulants are worthy of mention. He begins their use early and from the first twenty-four hours in some cases permits them as the only kind of food administered until all danger is past. He gives them early in order to avert or to mitigate the stage of collapse which is likely to ensue. With this general plan of treatment—bleeding, moderate purgation, opium to relieve pain, and the use of stimulants—his patients have usually recovered.

He thinks patients die of peritonitis generally, not because its management is not understood, but because it is not recognized sufficiently early. Hasty examinations without due regard to the local origin of the symptoms of the disease—and of these pain is usually the earliest—cause one frequently to overlook the actual condition of the case. Of this fact he gave two illustrations; the first patient he saw in consultation, the second at the autopsy; both were cases of peri-cæcal abscess. In one instance the patient was ill for four or five days before Dr. Musser's visit. Prior to the last twenty-four hours he visited his physician's office, simply complaining of recurring attacks of sharp abdominal pains, which were attended with a moderate amount of diarrhœa. The physician looked upon it as a case of cholera morbus, and treated it accordingly. The day of his death the patient did not leave his bed, but was visited by the physician, who was horrified to find him in collapse. The thready pulse, the persistent watery vomiting or regurgitation of fluid, the cold sweat and the cold extremities, the tympany and the rigid abdominal muscles, told the tale more

plainly than his words, and an area of dulness in the right iliac fossa, with faint local swelling and tenderness, pointed to the appendix as the probable source of the inflammation. Death ensued a short time afterward, and at the autopsy a most extensive peritonitis, secondary to rupture of the vermiform appendix and peri-cæcal abscess, was found. In the other instance the patient, a lad sixteen years old, was seen by the physician at six in the evening. In the hurry of his work he neglected the minute examination which he usually bestowed upon cases, and prescribed for what he thought was a colic, induced by indigestion, which colicky pains had been going on for two or three days, the patient, however, being out most of the time. He saw him later in the evening, much improved, apparently, from the effects of opium, and was shocked to hear the next morning that at six o'clock his patient had died in collapse. In this case foreign bodies in the appendix had caused the usual rupture, with peritonitis and death.

The most difficult question for the physician to decide, and the one that has always been the most serious in Dr. Musser's mind, next to the grave question of when to open the bowels, is when to ask the surgeon's help. Given a case with a palpable tumor, with local œdema, the fever, the vomiting and the general tenderness indicating a general inflammation, and the question is an easy one to decide. On the other hand, the tumor being obscure, possibly only an area of dulness outlines it, the symptoms, however, becoming threatening; shall we then ask for help? He himself invites surgical aid when persistent vomiting continues, when the night-sweats become marked, and when tympany and bowel obstruction are decided. After the second night-sweat, even if there is no general peritonitis, but physical signs or clinical phenomena of local disease, he is much disturbed. The increased frequency of pulse, or perhaps the signs of approaching collapse, which thus far in his cases he has not waited for, would induce him at once to ask for a surgeon.

He has never been impressed with the value of salines in peritonitis. In but one instance were they of any service in his experience, and this was after an abdominal section.

In the so-called cases of recurring peritonitis, if a second attack occurs, he advises at once operative interference, either before the attack has terminated or after the attack has subsided.

In corroboration of his remarks as to the value of the medical treatment of peritonitis, Dr. Musser quoted the experience of Dr. Girvin, who is a most careful, astute physician. He said recently that he had never lost a case of peritonitis, and that his plan of treatment is the use of some remedies to open the bowels, along with the use of remedies to allay the pain. To open the bowels he usually gives a pill containing a quarter or a half a grain of calomel, half a grain of extract of rhubarb, half a grain of aloes, with one-eighth or quarter of a grain of the extract of opium. Giving the pill early, he very soon secures a purgative effect, and when that is induced feels much more comfortable in regard to the welfare of his patient. He uses morphia by subcutaneous injection, and only in sufficient doses to keep the patient comfortable throughout the illness.

Dr. M. Price said: I do not believe that peritonitis is ever idiopathic. Call it by what name you please, it resolves itself into some irritation or lesion. Carbolic acid, almost pure, and phenol sodique, in its full strength, I have known to be poured undiluted into an abdomen after an operation. There will always be peritonitis after operations until so-called antiseptic surgery of the peritoneum is abolished. Mr. Tait is correct in saying that the opium treatment has its place only when you have given up all hope of curing the patient and want to make him comfortable. You make him perpetually comfortable. You not only put the bowels in splints, but the whole body in a fracture-box. Prof. George B. Wood, thirty years ago, advocated after bleeding, calomel, and purging with Epsom salts and senna, and perhaps somebody suggested it before him. But in recent times the credit of the saline treatment belongs to Mr. Tait, and Dr. Baldy does not claim it. Something was said of five days' treatment. The case should be in the surgeon's hands before that. There is already pus.

The tympany is of several kinds. The distention is often the cause of death. I have opened the belly and found a diverticulum adherent to omentum, with the intestine through it; the intestine was returned without difficulty; the distention was the cause of death. Many cases that recover are of such character. If we knew it, purging would be out of place. In operations when there are sharp pain and indications of inflammation, then we do not wait. We open the belly

and supply moisture. We pour in hot water—gallons of it—and give turpentine enemata and Epsom salts.

The bowels are already in splints. I have given six ounces of Epsom salts where ordinarily half an ounce would answer. As soon as free movement occurs the patient recovers.

Dr. C. B. Nancrede says he is a living specimen of recovery without section after an appendicitis. No one has here advocated the use of a drug valuable in the sudden collapse incident to the onset or in the later stages of some cases of peritonitis, when opium means death. That drug is atropine, hypodermically, in large doses. If opium is only to be given to relieve pain, this is not what was formerly understood by the opium treatment. It will not splint the bowel in mere anodyne doses, which was Alonzo Clark's original idea, and that of all his followers since. He disagrees with the men who would send for the surgeon to lock the stable door after the horse has escaped—in other words, wait, as is too often the case, until an operation is what is termed a "last resort," which amounts really to there being no reasonable chance for a success which an earlier resort to the knife would have very probably insured. The surgeon should be permitted to see the case *early*, and share in the decision as to when the operation should be done, when it should be postponed, and when declined; it is only by the chance afforded by a study of the *medical course* pursued by the case, that the surgeon can operate intelligently and successfully. He is using less opium as he grows older in all surgical work. He has tried the saline treatment of peritonitis in several cases after section, and has had no cause to regret it.

Dr. Joseph Price said: Dr. Meigs counsels delay. On the contrary, the earlier and simpler the operation the greater is the chance of recovery. I cannot, therefore, conceive any advice more unfortunate, more unjustifiable, for patients dying of peritonitis. In fact, the whole tendency of modern surgery is to anticipate exhaustion, shock, and collapse. The paper of Dr. Baldy referred to peritonitis, and not to pain and tenderness; and my remarks are devoted to peritonitis due to a recognized lesion, and not to pain and tenderness. The treatment of peritonitis resulting from external or infectious origin would be entirely irrational were drainage discarded. Once decide that the best method of clearing up a peritonitis is by operation, then drainage must follow that operation as naturally as sutures are used to close an incision.

If a peritonitis is septic in its origin, such as is seen frequently after criminal abortion, carelessness after miscarriage, and after gonorrhœal tubal disease, drainage is the third statement of the argument of operation:

1. Operation is required.
2. Douching and flooding the abdomen are necessary.
3. Drainage is the bulwark of the whole procedure.

That cases of infectious peritonitis recover without drainage is no more an argument against it than that some patients recover from small-pox, never having been vaccinated. If I use all the antisepsis possible before and during an operation, and at its close overlook the fact that I am leaving a possible infection behind, my antisepsis is only a parade, and misleading. If Listerism is the foundation of modern surgery, drainage is the keystone of its application in such cases of abdominal surgery.

Dr. Tyson said: I came to the meeting to-night attracted by the subject under discussion rather than to make any remarks, but I feel disposed to give expression to the general impression left upon my mind by this debate. I confess that when I heard Dr. Meigs portray his typical case of peritonitis I felt that the treatment he advocated would be the one I should always prefer to follow. Yet I do not think the parallel he drew between the state of the peritoneum in peritonitis and that of a "sore" is altogether justified. The inflamed peritoneum is rather to be compared to the earlier stages of inflammation in which we resort to leeching and depletion, and I have, by what has been said since, been strongly impressed by the rational character of the saline aperient treatment. It has the further advantage in quickly cutting short those doubtful cases in which a fecal accumulation is producing pain, the first symptom of inflammation, which disappears at once with its cause—the fecal mass.

I desire to call attention to a fact not mentioned, that rheumatism of the abdominal muscles sometimes simulates peritonitis so closely as totally to mislead. I have myself had this experience, and seen the symptoms yield with magical promptness to salicylate of sodium.

Dr. Meigs said: I cannot see why anyone should doubt the possibility of the occurrence of idiopathic peritonitis any more than of idiopathic pleurisy. There is

no reason, in the nature of things, why it should not occur, and that some physicians have not met with it is no proof that others who say they have are mistaken. Pleurisy, by extension of the inflammation, may be the cause of pericarditis, and in cases of diaphragmatic pleurisy peritonitis to some extent is a common secondary result. If there be diarrhœa, with inflammation of the mucous coat of the bowel, why should it not give rise to peritonitis? It seems to me that in the discussion the difference between peritonitis, as seen by those of us who are not surgeons, and the disease as a sequel of operations, has not been sufficiently kept in mind.

Dr. Baldy, in closing the discussion, said: Dr. Meigs and Dr. Musser believe in the opium treatment, and yet after giving opium for a few days they give purgatives. I should like to ask them what object they have in view when they give the purgatives, and what they expect to accomplish with them?

Theoretically it is perfectly possible to have idiopathic peritonitis. Practically, however, I have never seen it. Some of the gentlemen in discussing this subject seem to draw a line between the cases of peritonitis seen by the physician and those seen by the surgeon. Peritonitis is peritonitis the world over. It makes no difference whether it is set up by the surgeon himself or comes on idiopathically (so called): the result is always the same—inflammation of the peritoneum; the cause cannot alter the principles of treatment. My paper discussed peritonitis, and not simply pain and distention; as for an inflammation throwing out a bland fluid, I do not believe it. The products of inflammation are always irritating. Opium has been advocated here to-night in small doses and to relieve pain. In my experience small doses will not relieve pain. The dose must be comparatively enormous. Purgatives will relieve the pain as quickly as opium, and when once relieved it remains relieved, which it does not do with opium. If I were aiming at the relief of pain solely, I should most decidedly turn to my salines.

The objection has been made that salines give watery stools and do not carry away much feces. Of course, it is desirable that the fecal matter should come away, and so it does in great part. But large, watery stools are exactly what we desire to obtain. The whole principle of this treatment lies in its depleting powers. For this purpose the salines are given in large and *concentrated* solutions: they are peculiarly adapted to the early and highly inflammatory stages of inflammation. If purgatives are going to relieve, they will do so quickly, and we have no need of waiting for four or five days to know what to do next. Often, unless we use the knife, our patient is dead in five days. Recurring peritonitis always demands surgical interference.

Together with Dr. M. Price, I have but one use for opium in this disease—if everything else has failed, it is a good thing to give *ad libitum*, to ease the last hours of the patient.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of November 26, 1888.

The President, Alexander S. Hunter, M.D., in the Chair.

On taking the Chair for the first time the President read an address in which he referred more especially to the scientific purposes of the Society, and said it would be his object to obtain as good and as practical papers on practical subjects from able men as possible. He hoped the members of the Society would do their part and attend the meetings in large numbers.

The first paper was by Dr. William H. Thomson, on the

Significance of Cough and the Indications for the Use of Expectorants.

Dr. Thomson opened his paper with the remark that there is scarcely anything for which the physician is oftener called upon to prescribe than cough, and said that it is one of those things which, if not removed, many people look upon as the note of death. There is much to justify this dread. He does not think there is any class of prescriptions which the doctor, after some years, varies less than he does those for cough mixtures. But the habit is one least justifiable, since the indications for such mixtures vary greatly in different cases.

Dr. Thomson defines cough as a reflex act whose single motor or efferent mechanism is brought into play by a variety of afferent impressions. Its one important object is expectoration, but more frequently this proves useless. One of the commonest indications is to suppress useless cough and allow only that which will accomplish its purpose, expectoration.

The varieties of useless cough, he said, are not fewer than fourteen, and doubtless many more could be suggested. All useless coughs have one marked feature in common which distinguish them from expectorant cough. It relates to the sound; this in useless cough is always single, while in expectorant cough it is never so. If the non-expectorant cough were repeated, the sound would be like the distinct strokes of a hammer; while that of the expectorant cough is more like the sound of a chain passing over a pulley. Dr. Thomson accepts the observations of the Germans, which locate the sensitive points in the respiratory tract from the bifurcation of the trachea down to the second or third divisions of the bronchi. Fluids or foreign bodies below those points, or in the air cells of the lungs, do not excite cough; and in the trachea sensitiveness is present only in some states of inflammation. Passing to the larynx, other sensitive points are reached.

With regard to the varieties of non-expectorant cough, he first mentioned simple inflammatory irritation of the respiratory tract without secretion. The indication here, he said, is to turn the dry cough into an expectorant one as soon as possible; and among other remedies he uses tartar emetic in small doses in water. This cough, he said, is frequently present in chronic and acute bronchitis and in phthisis.

The co-existence of some secretion and more or less expectoration may lead one to overlook the non-expectorant cough. When there is an undue amount of the neurotic element, he gives chloral and morphine, which combination is preferable to morphine alone. It should be remembered, however, that these are drawbacks rather than advantages so far as the expectorant cough is concerned.

A second variety of useless cough arises from inflammatory irritation of the pharynx, and is common in ordinary colds, and also in advanced phthisis. The irritated parts may be benefited by the application with a brush of morphine mixed with starch, or by obtaining the specific effect of aconite on this mucous membrane. Another variety of useless cough occurs in irritation of the pleura. This origin of cough deserves, he said, special attention, and should lead the physician to adopt appropriate treatment to cure the pleuritic affection and avoid its results. Clinical experience shows that all serous inflammations are of serious import because of the conditions to which resulting adhesions may give rise. It is Dr. Thomson's custom in general pleurisy to strap the affected side, and to keep it strapped even as long as six months. Nothing else will do as much to stop the constant hacking cough. The same treatment is instituted in the annoying pleuritic cough of phthisis, when limited to one lung.

A specific useless cough is seen in whooping-cough. This, Dr. Thomson asserts, can always be stopped within a week by bringing about the constitutional effects of belladonna. If, however, a bronchitis is superadded there will be an additional cause for useless cough. A further variety of useless cough is the malarial, which is seen in children at night, and suggests whooping-cough. Quinine is indicated. Another variety is the nocturnal cough of children, due to intestinal irritation, as from worms, etc. The indications are plain. A seventh variety is called uterine cough, but the uterus need not itself be diseased to bring it about. It is seen also in hysterical women. When the uterus or its appendages are diseased, they should be treated accordingly; and, when the hysterical element predominates, valerian, bromides, etc., should be given. A purgative is often indicated. The aneurismal cough is best relieved by morphine, but it is surprising how often it can be warded off by a couple of leeches to the sternum. Then there is the useless cough due to pressure of an enlarged bronchial gland upon the pneumogastric. When the gland softens, the cough and the vomiting will both cease, but relief may be obtained in the meantime by dry cups between the shoulders. Foreign bodies in the auditory canal are mentioned in the books as a cause of reflex cough. There is also the useless cough from irritation of the phrenic nerve, from perihepatitis, etc. Cerebral cough is of importance, and is likely to arise from disease at the base of the cerebellum, from abscess, etc., pressing upon the medulla.

The indications for treatment of expectorant coughs are two, in some cases three. They are: to make the phlegm so liquid as to flow easily, and to make the cough sufficiently powerful to prove effective. The third indication, present in some cases, is to diminish superabundant secretion. In children with capillary bronchitis or pneumonia it is especially important to loosen cough and to overcome dyspnœa. There is an associate action between the œsophagus and respiratory tubes, and Dr. Thomson has found the frequent swallowing of half a

teaspoonful of milk and lime-water by these little patients of marked benefit in favoring expectoration and relieving dyspnœa.

The commonest indication in bronchial cough is to make the bronchial secretion more fluid, and the only unmistakable agent for this purpose is oil. All oils increase the watery flow from mucous membranes, and he has learned by experience that the most effectual for increasing the flow from the bronchial mucous membrane is linseed oil. It is best taken in emulsion, which is made in quantity by thoroughly mixing the following ingredients: Linseed oil, 15 ounces; oil of winter-green and cinnamon, each 2 drachms; powdered acacia, 10 ounces; water, 24 ounces; glycerine, 5 ounces; simple syrup, 10 ounces; dilute hydrocyanic acid, 2½ drachms. Half an ounce constitutes a dose. He sometimes adds to each dose three minims of Magendie's solution of morphine and eight grains of chloral.

Dr. A. Jacobi, having expressed doubt during the discussion as to our ability to diagnosticate pressure upon the pneumogastric nerve by enlarged bronchial glands, the author of the paper said it would hardly be possible to do so by auscultation or palpation; but the signs which he has relied upon are: vomiting; cough without expectoration; irritation of the stomach, with deep injection of the pharynx; aphonia without ulceration of the vocal cords; lastly, palpitation of the heart. This concatenation of symptoms, when present, points to pneumogastric irritation. His diagnosis has been confirmed in three cases by subsequent autopsy.

The paper was also discussed by Drs. Beverley Robinson, Clarence Rice, Simon Baruch, O. K. Tansley, and Darlington, who criticized some points, and referred to other varieties of useless or reflex cough, as from diseased conditions of the nose, of the external auditory canal, etc.

—Dr. Edwin R. Lewis reports to the *Boston Med. and Surgical Journal*, Nov. 29, 1888, that he recently delivered a woman of a female child which weighed 15 pounds and 2 or 3 ounces.

—About 150 refugees entered Jacksonville, Florida, Dec. 10, under the resolution of the Board of Health permitting entry provided the people go out of the city again at night. There have been no new cases of fever and no deaths. Pensacola and Escambia Counties, Florida, are to abolish quarantine against all places.

Foreign Correspondence.

LETTER FROM BERLIN.

Decadence of Classical Learning Among German Physicians.—Relation between Tabes Dorsalis and Heart Disease.—Propriety of Puncture in Hydrocephalus.—Extirpation of One-Half the Thyroid Cartilage.—An Early Sign of Phthisis.

BERLIN, Nov. 16, 1888.

The learned clinicians of the class of which Prof. Frerichs was the type, whose lectures bore witness to his classical studies, have of late become almost extinct in Germany. It is true, Frerichs' position as Chief of Internal Medicine has been filled by Prof. Gerhardt, from the Würzburg School of Medicine, who had acquired considerable fame through his writings about diseases of children, carcinoma, and some other affections; but the excellence of Frerichs' clinical and didactic work has never since been attained. It is said that Prof. Leyden, the famous neurologist, is a good representative of the classics in medical science as once taught by Frerichs; and, indeed, a clinical lecture by Prof. Leyden is as delightful as it is profitable. Your correspondent was invited last week to listen to Prof. Leyden's lecture on the connection between tabes dorsalis and heart disease, before the *Berliner Verein für innere Medicin*. The term tabes dorsalis is the name for locomotor ataxia used by German physicians, which has of late been also frequently used by English and French writers. The coincidence of locomotor ataxia and cardiac disease is rather rare, and it is only recently that the attention of clinicians has been directed to it. It is singular that in an affection as long and as well known as locomotor ataxia new symptoms of importance should continually be described. Among these recently observed symptoms of tabes dorsalis the so-called visceral complications, described by Charcot under the name *crises gastriques*, claim our special attention. Charcot was the first to discover a connection between vomiting and tabes. At the same time he noted intestinal, urinary, respiratory, and even cardiac symptoms arising in connection with the disease. He observed the quickened pulse in tabes as a permanent symptom. Besides, there were found to occur valvular lesions and angina pectoris. Berger and Rosenbach were the first to call attention to valvular disease in the course of locomotor ataxia, and also to the interesting question whether there is an

etiological connection or a mere coincidence between the two affections. It seemed probable that the cardiac branch of the pneumogastric nerve became affected and thus secondarily led to valvular affections. Berger and Rosenbach report seven cases of locomotor ataxia accompanied with symptoms of pronounced insufficiency of the aortic valves. Viewed pathologically it would appear as if these valvular lesions were connected with the various trophic changes occurring in tabes, such as muscular atrophy, perforating ulcer of the foot, degenerative changes in the joints (athropathy), and skin-eruptions. Analogous trophic changes may lead to degeneration of the valvular apparatus. If this, however, were true, it would be an occurrence without analogy in medicine. Besides, the two affections are sufficiently common, especially in middle life, to warrant the belief in a mere coincidence rather than in a pathological connection. Mitral lesions have also been observed, by French writers, to occur simultaneously with locomotor ataxia. In the decision of the question whether we have to deal with a mere coincidence or not, of the greatest importance, of course, is the autopsy. If the *post-mortem* examination reveals no signs of arterio-sclerosis, the etiological relations between tabes and the valvular lesion would appear certain. Prof. Leyden's last patient in whom both tabes and valvular disease were observed, was a woman 48 years of age, a seamstress, hard-working, but in rather good health. Twelve years ago she first noted rheumatic symptoms, and for the last two years she was affected with dyspnœa, which ultimately necessitated her removal to the Charité. The pulse was 100, bounding and large. Near the apex there was a distinct diastolic murmur. There were no important nervous lesions and no disturbances of coördination; the knee-jerk was absent. The autopsy showed enlargement of the heart and dilatation and hypertrophy of both ventricles. The aortic valves were thickened and retracted, the papillary muscles thin and relaxed. The aorta was wide just above the valves, the intima thickened just at the arch. The spinal cord did not show any macroscopical lesion except a thickening of the arachnoid. We have now to decide, said Prof. Leyden, both from the clinical history and the result of the autopsy, whether the valvular lesions refer to an arterio-sclerosis or are to be regarded as a complication of tabes. The former evidently is the case. Prof. Leyden is, therefore, not of the opinion that the valvular lesions observed in the course of locomotor ataxia have any internal connection, but thinks that they are merely coincidental.

At the last meeting of the *Berliner Medicinische Gesellschaft*, Dr. Ehrmann presented a case of hydrocephalus and raised the question whether puncture is beneficial or harmful. Prof. Henoch, the eminent specialist in children's diseases of the Charité, replied that he often—five and even six times in one and the same case—performed the operation of puncture and subsequent compression, and that he had never seen any injurious results proceeding from it; but at the same time he never saw any benefits from it.

Prof. Küster presented a patient one-half of whose thyroid cartilage he had extirpated. The patient had a surprisingly good voice, and Prof. Küster explained that owing to a cold the patient's voice was less distinct than usual, and that it would become still better than it then was. His advice is to retain the thyroid cartilage in all cases, if possible. Dr. Kayser, of Breslau, spoke of the death of his brother, which resulted from the extirpation of a portion of the larynx, the seat of a carcinomatous ulcer similar to that in the case of the Emperor Frederick.

Dr. Sticker, of Munich, calls attention to a new and readily recognized symptom of phthisis, viz., a bright red line of demarcation between the teeth and the tongue. Sticker has examined one thousand patients for the purpose. He states that the symptoms which may precede tuberculosis, such as pseudo-chlorosis, dyspepsia, etc., are very probably the expression of latent phthisis, if the red line is present, and especially in young persons. The absence of the line, especially in female patients, is of no importance. In acute phthisis the line is of a bright red color; in chronic phthisis of a bluish, and in pronounced scrofulosis of a white color.

J. S.

—An outbreak of scarlet fever in Glasgow has been traced to a dairy; fourteen of the ninety-two families supplied from this dairy were found to be infected.

—Some physicians in Brooklyn have been swindled recently in the following way: During the absence of the physician a man calls and offers a check in payment of an imaginary bill less in amount than the face value of the check; the latter is, of course, spurious.

PERISCOPE.

Induction of Premature Labor.

M. Bayet, interne in Prof. Kufferath's clinic in Brussels, describes in *La Clinique* an attempt made under the Professor's direction to induce premature labor by means of the so-called elytro-pterygoid apparatus of Chassagny. This apparatus, about which a good deal of discussion has recently taken place in Belgium, consists essentially of a pig's bladder, which is folded up and introduced into the uterus, and subsequently distended by means of the injection of water, similarly to the "colpeurynter" which is used in German clinics. The patient in M. Bayet's case was a young woman of strong constitution, but with a rachitic pelvis, the conjugata vera being only six centimetres and a half, as measured by Van Huevel's pelvimeter. The woman was in the eighth month of pregnancy. M. Kufferath gave her the choice of having premature labor induced at once, or of waiting until her full time, and then submitting to Cæsarean section, with the hope of bringing forth a living child. She naturally selected the first of these alternatives. With this object Chassagny's apparatus was introduced and allowed to remain for half an hour in the uterus; it caused, however, severe pain, and was extremely difficult to keep in its place, besides which it produced erosions in the vagina, causing a bloody discharge. Further attempts were subsequently made, but these proved so painful and caused so much ulceration and œdema of the vagina that they had to be discontinued and the patient left alone for five or six days. These attempts to produce premature labor having entirely failed, a soft bougie was introduced, and in three or four days' time with a successful result. An attempt was made to deliver the woman with forceps, but the head refused to engage the brim. Tarnier's basiotribe was therefore applied, and the head crushed in all directions, after which extraction was easily effected. The patient made a good recovery. M. Bayet remarks that Chassagny's apparatus gave a very different result from that described by M. Hubert, who reported that he had been able to induce premature labor in an hour by its means. M. Bayet also remarks that it is impossible thoroughly to disinfect an apparatus composed of a pig's bladder, especially as it is necessarily introduced folded up, and therefore full of creases. Regarding the effect of the basiotribe, it is noteworthy that the child when born was, legally speaking, alive, its respiratory and cardiac movements continuing, indeed, for about two hours, besides which it cried faintly. Of course, as the brain was completely reduced to a pap-like mass, life, such as it was, depended entirely on the medulla oblongata; still it is well to remember that in delivery by means of cephalotripsy it is possible that the child may be born "alive," and may therefore inherit property.—*Lancet*, Nov. 3, 1888.

Tuberculosis of Ovary.

At the meeting of the Pathological Society of London, Nov. 6, 1888, Dr. Griffith showed sections of an ovary the seat of tubercular disease. It was removed by Dr. Galabin from a nullipara nineteen years old, was as large as a small apple, dense on section, and contained numerous small cysts filled with viscid fluid. Examination revealed a rather dense well-developed connective-tissue stroma infiltrated with small round cells and containing scattered spherical nodules resembling well-formed non-caseating tubercles. Each of these was bounded by circularly arranged connective tissue, which was prolonged by branching processes into the centre, which latter was occupied by a giant cell often multinuclear. There was no appearance of caseation in any part. A few newly developed bloodvessels were seen traversing the section, but they did not appear to enter the nodules; there was little if any normal ovarian stroma left. The peritoneal surface was thickened, and consisted of fibrous tissue invaded by leucocytes. The fibro-muscular wall of the Fallopian tube was expanded, the mucous membrane being thick, consisting almost entirely of tissue similar to that of the ovary, and containing but few tubercles. No microörganisms were found in the giant cells or the surrounding tissue. The tubercles all appeared to be of recent formation and rapid growth. Reference was made to the scanty literature on the subject, there being two chief forms of tubercular ovarian disease described: (1) minute miliary granulations, chiefly near and on the surface of the organ; and (2) larger caseous masses. It occurred usually as a part of a general tuberculosis. The most common seat of tubercle in the female generative organs is the Fallopian tube, then the uterus, and lastly the ovary.—*Lancet*, Nov. 10, 1888.

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CONGENITAL STENOSIS OF THE PYLORUS.

Some time ago Landerer and Mayer suggested that stenosis of the pyloric orifice of the stomach which attracts attention in adults, may be due to a congenital defect. This idea was founded upon purely theoretical considerations, and they had had no opportunity to confirm or correct it by actual observations. Since then, as is noted in the *Centralblatt für die med. Wissenschaften*, Nov. 3, 1888, Hirschsprung has found two cases which have been regarded as lending support to this theory. One was that of a well-nourished infant, who was healthy up to the tenth day, and then began to suffer with frequent vomiting and obstinate constipation. On the thirtieth day she died; and at the autopsy the lower part of the œsophagus was found to be moderately dilated, the wall of the stomach to be thickened, and the pyloric portion to be thickened and indurated and its lumen to be narrowed so that only a medium-sized probe could be passed through it. The second case was that of an ill-nourished girl, three months old, who had always suffered with vomiting, and occasionally with constipation. Death occurred, from phthisis pulmonum, when she was six months old. At the autopsy the stomach was found to be dilated and its walls hypertrophied; while the pyloric portion was much thickened, and scarcely permitted the passage through it of a lead-pencil.

These two cases are interesting as pathological curiosities; but they can hardly be considered as demonstrating the correctness of the theory spoken of above. Those who study them critically will, we think, conclude that they do not prove anything except that stenosis of the pyloric orifice of the stomach may exist at a very early age, and that it may even be congenital. This is a very different thing from the assumption that stenosis may exist for years, and all the while permit such a state of health that it shall not be suspected. For the present, the most that can be said on the subject is that it would be interesting to note carefully and systematically the condition of the pyloric orifice of the stomach in autopsies on young children, in order to determine the proportion in which stenosis occurs; and to study the history of patients in whom stenosis is diagnosticated in adult life, with a view to discovering evidence that it has already been present for a long time. Whatever may be the effect of such studies upon the theory of Landerer and Mayer, it is well for American physicians to know that it has been advanced by able and well-known observers, and to bear it in mind when cases of stenosis of the pylorus come under their notice.

SAVING THE PERINEUM.

Rupture of the perineum, its causes, frequency and methods of prevention must ever be questions of practical moment to the obstetrician. The man who in an extensive obstetric experience has never encountered rupture of the perineum is no longer regarded as a marvel of skill, but simply as a man who has failed to examine the perineum at the conclusion of labor. Olshausen distinguishes two varieties of rupture of the perineum: inevitable, occurring in spite of the greatest precautions; and avoidable. According to this authority, inevitable laceration of the perineum—not including tears of the *fourchette*—occurs in fifteen per cent. of primiparæ; and the result of his observations extending over ten years shows that laceration occurs in twenty-one and one-tenth per cent. of primiparæ, and four and seven-tenths of multiparæ. A competent critic has remarked that if such results have been obtained in his hands, the higher figure must represent the actual per cent. of inevitable lacerations, since surely all that science or art could do for these patients was done. Schroeder gives twenty-seven and seven-tenths as the per cent. of lacerations in all cases. Winckel gives twenty per cent. Charpentier quotes these and similar statistics as showing the frequency of laceration. These figures indicate the accepted opinion in Continental Europe, as to the frequency of laceration of the perineum. English obstetricians have great faith in this or that method of treatment, as preventing laceration, but fail to emphasize this belief by statistics, and at the same time admit that laceration is very common. In the American text-books the German statistics are quoted with approval Lusk, Parvin and Busey (Amer. Syst. Obstet.) all quote Olshausen's figures in particular. We may conclude, then, that it is practically the universal belief of obstetricians, that about every fifth primipara and every twentieth multipara will inevitably suffer from laceration of the perineum in labor, aside from tears of the *fourchette*.

A discussion upon this subject was recently brought out, in the Obstetrical Society of New York, by a paper from Dr. McLean, entitled "Some Remarks on the Duties of the Modern Obstetrician" (*Amer. Journ. Obstet.*, Aug., 1888). In discussing the conduct of labor during the time that the head is distending the perineum, the writer states that he is convinced "that any so-called support which is directed to the perineum itself is worse than useless. It merely increases the danger of laceration." He believes that pressure upon the presenting part is not sufficient, though it may assist in preventing rupture by delaying the moment of maximum strain. He is "satisfied that we can do the most good by making our pressure at a point on either side of the median line, *posterior to the anus*, near the coccyx, and in such a direction that not only the presenting part is crowded toward the pubic arch, but the whole group of perineal tissues is dragged forward so as to relax them to a degree." He considers the administration of chloroform of value at this time, since it helps to relax the perineum and to control the voluntary expulsive efforts, and at the same time it safely mitigates the sufferings of the mother. Nor should the obstetrician relax his vigilance with the delivery of the head, since the shoulder or elbow of the child may plow through a part which has escaped head pressure.

Dr. Polk insisted upon the importance of securing entire delivery of the occiput from under the pubic arch before allowing complete extension to occur. In this way the sub-occipito-frontal and the sub-occipito-mental diameters engage at the vulvar orifice.

Dr. Lusk stated that "if a woman has a healthy vulva and no inflammatory condition it is always possible to guide the head through it without causing laceration of the perineum." He endorses the method of

delivery mentioned by Dr. McLean, and believes that the main thing in preventing laceration is to ensure a slow descent of the head. Upon interrogation, he reiterated his statement that if the perineum is "in a healthy condition" laceration is unnecessary, and said that when it had occurred in his practice under these conditions it was because he was in a hurry.

Neither Dr. Dudley nor Dr. Mundé believed it possible to prevent laceration always—at least it had not been in their practice. Mundé related a case in which although he succeeded in delivering the occiput without accident, yet it was not possible to prevent laceration during extension of the head.

The emphatic declaration of Dr. Lusk attracts attention. Either he has changed his mind since the publication of his treatise on obstetrics, or else it would seem that his estimate of the proportion of abnormal or unhealthy vulvæ is high. Nevertheless, we think that the promulgation of the opinion of so capable an observer, as to the value of proper treatment in preventing laceration, will do good; because just at this time there is a growing scepticism concerning the importance of any treatment looking toward the prevention of this accident.

We bring this discussion before our readers as representing the views of some of America's distinguished obstetricians, and we entirely agree that the principles and methods of treatment here laid down are the best in the majority of cases. But this is not true in cases of tedious labor, in which the head is long delayed at the pelvic outlet owing to a lack of relation between the resistance of the perineum and the propulsive forces of the mother. Here delay only favors stasis of blood in the maternal tissues, with œdema, and possibly, later on, sloughing. The life of the child is also endangered by long-continued pressure upon its head. Under these circumstances the use of the forceps is indicated not only as conserving the life of the child, but also the integrity of the tissues of the mother. Moderate traction can be made during the pains, or, in cases in which pains are absent, at regular intervals—the head being allowed to recede between the traction efforts. In this way, the perineum is gradually distended, and the child delivered with the least danger to the integrity of the maternal tissues.

LUNG SURGERY.

A very remarkable case of lung surgery was reported by Prof. Hofmokl to the K. K. Gesellschaft der Aertzte in Vienna, November 16, 1888. The patient was a man, 32 years old, who had decided symptoms of gangrene of the lungs. The seat of the gangrene was located at the back part of the right lung. A portion of one of the ribs about two and a half inches long was excised, and with the Paquelin cautery four punctures, about two inches deep, were made in the lung tissue. As no air or pus escaped, Hofmokl then made a puncture about three inches deep, from which air escaped. The wound was covered with an iodoform dressing, and Hofmokl, feeling that the operation had not been successful, expected the patient to die. But, to his great surprise, the patient at once began to mend, and before long left the hospital cured.

This interesting case may have been one —as was suggested in the discussion which followed Hofmokl's report—of putrid bronchitis; but, in any event, it cannot be doubted that the operation saved the patient from imminent death.

Such operations are nowhere very common, although they have been, and are, more frequently resorted to in Europe than in this country. This is partly due to the fact that European hospitals seem to present more occasions for desperate operations than do those of our own country, and partly to the fact that operations upon the lungs have never become the fashion here, as they have become to a certain extent

there. But it is well to note what is going on across the water, and to bear in mind the successes which have been achieved in the treatment of serious diseases of the lungs by bold and skillful operations; for no medical man can tell when a case may present itself in his own practice, when his patient's life may depend upon his knowledge of what may be undertaken for the relief of the condition present, and his courage to undertake it.

OPENING OF THE PASTEUR INSTITUTE.

The foreign medical journals bring the details of the exercises connected with opening of the Pasteur Institute in Paris, November 14, 1888. On this occasion addresses laudatory of the work of Pasteur were read, and Pasteur replied with characteristic modesty. An important part of the exercises was an address by Prof. Grancher, in which he repeated the familiar claims for Pasteur's method of inoculation for the prevention of the development of rabies, and pointed with satisfaction to the existence at this time of twenty-one institutes for the practice of Pasteur's method in various parts of the world.

We have not at hand the means of revising fully the list given by Grancher; but it is interesting to note the old symptom of inaccuracy, in his statement that a Pasteur Institute is located in a city so near and so easy to know about as Vienna. As the *Wiener med. Presse*, Nov. 18, points out, only one medical man in Vienna, Dr. Ullmann, ever practised Pasteur's inoculation on human beings, and his attempt to establish a Pasteur Institute proved an utter failure. In mentioning this fact, the *Wiener med. Presse* adds: "It is to hoped Herr Grancher is better informed in regard to the other Pasteur Institutes."

Those who share our opinon in regard to the method of Pasteur for the cure or prevention of hydrophobia, and of the way in which its general adoption has been urged upon the world, will not be surprised at any new evidence of carelessness in the arguments of his nearest defenders. So far as rabies is concerned, we expect nothing from the Pasteur Institute; although we sincerely hope that it may develop into a useful laboratory for the study of bacteriology.

TYPHOID FEVER IN DRINKING-WATER.

It is reported from Brooklyn that there is an epidemic of typhoid fever in that city, and this report has led to an explanation by Dr. Charles F. Chandler that the cases of typhoid fever are to be attributed to water drunk by the patients at a distance from the city, and that it is not attributable to the drinking of Croton or any river water. It is interesting to note this important discovery at a time when typhoid fever is prevailing in what is practically a part of New York City, in view of the well-known fact that when typhoid fever occurs in more than minimum proportions in the city of Philadelphia, our neighbors in New York rarely let slip the opportunity to charge the outbreak upon the maligned but patient Schuylkill.

PAMPHLET NOTICES.

[Any reader of the REPORTER who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

163. THE CONTAGIOUSNESS OF PHTHISIS (TUBERCULOUS PNEUMONITIS). BY LAWRENCE F. FLICK, M.D., Philadelphia. From the *Transactions of the Med. Soc. of the State of Pennsylvania*, 1888. 21 pages.

163. Dr. Flick's paper is one which deserves most careful and impartial study by all who are interested in the important subject of which it treats. It contains an elaborate argument for the contagious character of tubercular phthisis, full of the evidences of painstaking research and thorough analysis. One of the most interesting portions of his address describes the results of a minute investigation of the developments of phthisis in the Fifth Ward in Philadelphia, and is accompanied with maps showing the number of cases which he has located in the different houses in this locality. To be frank, we are not convinced of the soundness of Dr. Flick's conclusions, although we admire the patience and zeal with which he has worked to get at the truth in regard to the contagiousness of phthisis; and commend his excellent paper to the attention of our readers.

CORRESPONDENCE.

Prevention of Conception.

TO THE EDITOR.

Sir: Since my brief paper with the title of "Professional Cowardice" appeared in type, so many letters have come to me with reference to the same, that I am impelled once again to intrude upon your time and patience.

Two things impress me with much force, when I glance at this pile of correspondence before me, which bears post-marks ranging in longitude from Florida to California and in latitude from Canada to Mexico. The first is wholly flattering to your admirable journal, which unquestionably takes place among the very first in circulation and influence. The second is, that there can be no doubt that a larger and better knowledge concerning the sexual hygiene of the family is very generally desired.

Now when I assure your readers that a large percentage of these communications come to me in the form of appeals from physicians themselves who are over-burdened with fast-increasing families, is it not evident that a most important special branch of our art has been neglected in their education? And if medical men, with their knowledge and training, are unable to "reduce (or rather prevent) the surplus," need we be suprised that the laity are clamorous for information as to how they may limit their progeny?

Many of the letters I receive come from those outside the profession, and I am fully convinced that if I were to advertise an "infallible preventive," I might soon emerge from my present obscurity and gayly climb the stair of fame and opulence. The subject, however, is worthy of a more dignified and serious treatment than this; and if the REPORTER will allow me space I will endeavor to further the cause of morality by disclosing the method which has proved most effectual in my hands.

To begin the subject, it may be well enough to mention the various more or less fashionable methods of preventing pregnancy now in vogue. The most common is the use of the syringe, in some form or another. In Great Britain and America this method holds first place. It has a certain value, provided it is resorted to immediately after the conjugal act, and if a strong astringent is added to the menstruum, in order to destroy the spermatozoa. If, however, the sexual feeling is strong and perfectly reciprocal, as is the case where conjugal relations are normal and complete, this method is valueless; for, during the act, the womb, sensitively alive to its function, presents an open os to the impinging male organ. There is even reason to believe in a positive act of suction on the part of the cervix; hence, during the orgasm the seminal fluid finds its way directly into the cavity of the womb, where of course, the sequel is beyond the reach of any injection.

Another objection to the use of the syringe is the risk incurred in leaving a warm bed, glowing hot from the act of intercourse, to cross a cold floor, it may be in bare feet, and—as if this were not risk enough—proceeding to deluge the sensitive parts with possibly ice-cold water.

Another method that has grown in popularity of late is sometimes called "conjugal onanism." In this procedure the male organ is withdrawn just prior to ejaculation. This is effectual, and is not as a rule hurtful; but, for certain æsthetic reasons, which I have no need to particularize to the initiated, is an utter abomination. The same feeling is intensified in contemplating the *capote* or condom; and as to the various "veils," and inventions of that sort, for the female, the degree of skill required for their adjustment practically puts them out of the question.

To confess the truth, there is much in the subject to offend a refined and delicate mind, looking at the matter in as favorable a light as can be thrown upon it. It is a hateful thought that coolly calculates results, when true conjugal love demands a sacrifice. However, this is a practical age and sentiment has sometimes to be put aside or overcome; and so I will communicate to the readers of the REPORTER the method which, in my hands, has proved most satisfactory.

The appliance is a sponge, preferably a silk sponge, although a sheep's-wool sponge will do very well. There is no need to shape it in any peculiar way; the nearer it comes to the form of a ball the better. It is important to have it of a sufficient size, which will average, as a rule, one and a half cubic inches or possibly a trifle more. A strong silk thread should be passed through it and the returning loop should include enough of the sponge to prevent the thread from tearing out. The two ends must be knotted together, and, for convenience, they should be from ten to twelve inches in length.

This is all there is of the apparatus; and all that is needed for its use is that the

wife shall bear in mind that it is just as much a part of her night attire as is her *robe-de-nuit*. No skill is needed in arranging the affair. It is simply moistened and inserted a little way into the vagina; and at the needed time, it will be carried onward, covering and shielding the os uteri, while its meshes will catch and hold the seminal fluid. It is not absolutely necessary that it should be removed before morning; though, if convenient, it would be well to take this additional precaution. Here the knotted silken string will demonstrate its usefulness.

It may be suggested that this is a remarkably small mouse to result from the throes of so considerable a mountain. As to that, so much the better. The simpler and less expensive the appliance is, the better, provided the results are satisfactory; and that this will prove to be the case, I feel safe in promising.

Yours truly,

DAVID E. MATTESON, M.D.

Warsaw, N. Y.,
Nov. 29, 1888.

American Volunteer Medical Corps.

TO THE EDITOR.

Sir: Since my return home from Jacksonville, Fla., where I have been a volunteer physician for eight weeks, I have been looking over my REPORTERS that have accumulated during my absence, and I find that no mention has been made of an organization that was formed there on October 1, 1888, known as the American Volunteer Medical Corps, whose object is to be prepared to place at the service of any city afflicted with an epidemic the professional assistance of twenty-five reputable physicians who are considered experts in yellow fever.

The class of men who flock to cities when thus afflicted have always been below the standard, and knowing this from past experience we determined to make an organization that could be depended upon.

Dr. Jos. Y. Porter, of Key West, Fla., Ret. Surg. U. S. A., was elected President, with Drs. Thos. E. Broaddus, of St. Louis, Mo., and B. F. Shiftall, of Savannah, Ga., as 1st and 2d Vice-Presidents, Dr. P. H. Strausz, of Palatka, Fla., as Secretary, and Dr. L. C. Carr, of Cincinnati, Ohio, as Corresponding Secretary. Our membership is limited to twenty-five active members, and we have now fourteen. The requirements for membership are that a physician shall have passed through at least one epidemic as a *volunteer*, shall have a diploma from a regular, recognized medical college, and have a good moral character.

Knowing the progressive nature of the REPORTER, and thinking that a piece of news like this would be kindly received, I have taken the liberty of addressing you with the hope that you will give it space in your columns.

Yours truly,

PHILIP H. STRAUSZ, M.D.,
Sec. A. V. M. C.

Palatka, Fla.,
Dec. 1, 1888.

Dr. Corson's Resolutions on Hospitals for the Insane.

TO THE EDITOR.

Sir: In your issue of Dec. 1, Dr. Hiram Corson publishes the resolutions offered by him at the meeting of the Medical Society of the State of Pennsylvania in June last, with the statement that "the Publishing Committee by an unwarrantable assumption of power has excluded them from the Transactions." The resolutions in question were not "excluded" by the Publication Committee; they were simply never offered to it for publication. They might with propriety have appeared in the minutes of the meeting, but did not, as these minutes came to the Publication Committee; and the Committee has no authority to alter the minutes, either by exclusion or inclusion. Why the Secretary omitted them from the minutes, I do not know. But it may have been because they had been printed before, in the Transactions for 1886, page 36.

Yours truly,

EDWARD JACKSON, M.D.,
Chair. Publication Committee.

Philadelphia,
Dec. 8, 1888.

NOTES AND COMMENTS.

The Dosage of Chloroform.

Mr. Alex. G. R. Foulerton, in a note on the dosage of chloroform (*Lancet*, Nov. 3, 1888), says that his own rule is never to administer it at a faster rate than a drachm in five minutes; and after complete anæsthesia has been induced, the quantity necessary to maintain that state falls in inverse ratio to the length of time that the operation lasts. He believes that this rule is in accordance with the practice of most of those who are in the habit of administering chloroform to any extent.

Raising the Epiglottis by Extreme Extension of the Neck.

In a paper read before the Medical Society of London recently, Dr. Benjamin Howard described a "New and Only Way of Raising the Epiglottis." This way consists in making the utmost possible extension of the head and neck. Dr. Howard has evidently made a most thorough and scientific study of the subject, but his studies simply demonstrate conclusively what has long been known and practised empirically on this side of the Atlantic, more especially, perhaps, in Baltimore. His paper will fulfil a most useful purpose, however, by bringing the method to the notice of many who have been up to the present time in ignorance of it. Of course the most common occasion requiring the raising of the epiglottis is obstruction to the breathing during the administration of an anæsthetic.

Pyrodin: A New Antipyretic.

Dr. Dreschfeld, Professor of Pathology in Victoria University, Manchester, communicates to the *Medical Chronicle*, November, 1888, some clinical observations on pyrodin, a new antipyretic. He describes it as a white crystalline powder, very sparingly soluble in cold water; it possesses very little taste, and is, therefore, easily administered in the form of powder. After trying it in doses of eight and twelve grains for several consecutive days on healthy persons, and finding that it was easily taken and produced no ill effects, he began trying it on patients suffering with various forms of fever. The results obtained in these experiments, briefly stated, show that pyrodin is a powerful antipyretic; it reduces temperature quickly, and maintains it at a low level for some hours. It is easily taken and produces marked perspiration, but neither nausea, vomiting, nor collapse. It is especially applicable in cases of pneumonia, scarlet fever, and typhus fever. Given in small doses in the latter disease it enables the patient to pass through the fever period at a lower temperature range without delaying the crisis, and it seems also to shorten the period of convalescence. It is less applicable in cases of typhoid fever, owing to the early appearance of toxic symptoms. It appears to act equally well in migraine and neuralgia, though on this point his observations are not yet numerous enough to admit of a definite opinion. Given in frequently repeated doses at short intervals, it easily shows toxic properties, which depend on the action of the drug on the blood, producing hæmoglobinæmia. It should not be given (unless the temperature is very high) oftener than once in eighteen or twenty-four hours, and it is not safe to continue its use for more than a few days. It is found to act in cases in which the other antipyretics have failed. The dose for children is two to four grains; for adults, eight to twelve grains. It is a much more powful antipyretic than either antipyrin, antifebrin, or phenacetin, but it is also much more toxic than these bodies. This disadvantage is, however, reduced by the fact that it is rarely necessary to give more than one dose in twelve or eighteen hours, as the temperature is kept low for a longer period than if any of the other antipyretics are given. Finally, it reduces the pulse as well as the temperature, and often causes diuresis.

Ethics of Medical Journalism.

A large number of eminent members of the British Medical Association and others recently directed the attention of the President and Council of the Association to the publication in the *Journal* of the Association of a *fac-simile* of a "script" by the late Emperor of Germany, referring to his treatment by one of his medical attendants. The publication of this document they regarded as a violation of professional confidence, and its appearance in the *British Medical Journal* as discreditable to the medical profession of England. They accordingly requested the President and Council to take such immediate action as may seem to be required to clear the Association and profession from the discredit attached to them in respect to this matter.

At a special meeting called in response to the memorial just quoted, the following resolution was unanimously adopted:

"That this Council strongly deprecates the publication of any details in violation of professional confidence. The Editor of the *Journal* has given to the Council his assurance that he had reasons which he considered adequate for believing that the publication of the 'script' referred to in the protest laid before the Council was not a breach of confidence, but has expressed his regret at its publication in the *Journal*. The Council would express their own regret that, under any circumstances, that document was published."

Guild of St. Luke, Evangelist and Physician.

The purpose of this Guild, which is composed of students and practitioners of medicine, and of the clergy of the Protestant Episcopal Church, is to encourage medical students to attend religious services, and to promote and defend the Christian faith amongst members of the medical profession, both by frequent and regular communions, intercessory prayer, personal influence, and by works of mercy. It is the intention of the Guild to arrange for special services for the students, to be held on Sunday evenings at different churches in rotation. Further information with regard to the Guild may be obtained from T. Ridgway Barker, M.D., 423 S. Broad Street, Philadelphia, Secretary of the National Council.

The object of the Guild is an admirable one. Students far from home in a large city are exposed to many temptations, and are not infrequently in need of just such services as it is the avowed object of this Association to furnish.

NEWS.

—Typhoid fever is said to prevail to a considerable extent in Camden County, N. J.

—Dr. Joseph W. Howe has been appointed Consulting Surgeon to the Charity Hospital, New York.

—Dr. Henry Leffmann has been elected Pathological Chemist to the Jefferson Medical College Hospital.

—There has been another heavy frost at Jacksonville, Fla., and yellow fever is believed to be at an end.

—Dr. M. J. Reinfelder, Consulting Physician to St. John's Riverside Hospital, at Yonkers, N. Y., died Nov. 30, of heart disease.

—Measles is reported to be epidemic in Limestone, Me. Chicken-pox is also prevalent. Schools are closed, and communication with other towns has almost entirely ceased.

—The statement concerning a remarkable consultation by telegraph, which was published as a news item in the REPORTER Dec. 1, on the authority of the *Medical Record*, is a mistake, no consultation in a proper sense of the word having occurred. What actually did occur appears from a note in the *Lancet*, Dec. 1, which states that it has been "requested by Sir Donald Smith, K.C.M.G., a gentleman in London interested in the case of Lord Ennismore, to give the true version of the circumstances upon which it (the story) was based. It appears that Sir Donald Smith on Sunday, the 18th (November), asked Sir Andrew Clark, when attending him professionally, to accompany him to the Central Telegraph Station in order to assist him in interrogating the doctors in Victoria in medical charge of the patient as to his exact condition, in order that precise information might be conveyed to Lord Ennismore's family. Sir Andrew replied that he could not consent to that course, but would write down for him on paper the questions which would elicit the information he required. This was done, and in the transmission of the cablegram the name of Sir Andrew Clark was in some way inadvertently associated with the message, and the telegraph authorities on the other side used it for the purpose of concocting the story. There was therefore no 'consultation' in the proper sense of the word, the only part taken by Sir Andrew Clark in this matter being the assistance rendered by him to Sir Donald in framing the message."

HUMOR.

WHEN THE DOCTORS GIVE YOU UP, there is only one way to get well; and that is to give the doctors up.—*Fliegende Blätter.*

A SURE SIGN.—"What an intellectual couple Mr. and Mrs. Cranque are!" "Intellectual? What makes you think so?" "Why, Mrs. Cranque cuts her hair short, and Mr. Cranque lets his grow long."—*Harper's Bazar.*

DOCTOR (passing a stonecutter's yard)—"Good-morning, Mr. Jones. Hard at work, I see. I suppose you finish your gravestones as far as 'In Memory of' and then wait for someone to die, eh?" Stonecutter—"Why, yes; unless somebody's sick and your doctoring 'em; then I keep right on."—*Chambers' Journal.*

AMBIGUOUS ANATOMY.—Scene: Pharmacy. Enter an elderly female to whose husband some of our "Kill-Pain Liniment" has been supplied. Chemist: Well, Bridget, is Michael better? Mary: Deed he's not thin, dochter avic. I rubbed in yer medicine, but he got no betther, so oi brought him to Vincint's this morning, and Dochter McArdle, the jewel, ses he has an abyss in his slumberin' verterbrin, near his spinal columns.—*Chemist and Druggist.*

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

Clinical Lecture.

ANTERIOR URETHROTOMY FOR GLEET.

BY EDWARD L. KEYES, M.D.,

PROFESSOR OF GENITO URINARY SURGERY, SYPHILOLOGY AND DERMATOLOGY IN BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

Gentlemen: Anterior urethrotomy, especially for the treatment of gleet, is the subject which we will consider to-day. There will be little time to devote to the cases operated upon a week ago—hydrocele and phimosis—for the subject of anterior urethrotomy is veiled in so great obscurity, there is such marked difference of opinion regarding its indications, that an hour will prove too short more than to mention the disputed points. The operation itself is a trifling matter; it is very simple to perform, but when to resort to it is a question of more difficult solution.

First, however, I will present you the young man on whom I operated last week for varicocele. He had no trouble after the operation; no medicine was administered. He simply lay abed four or five days, and the result has been perfect. He is practically cured; the scrotal veins will no longer serve as broad receptacles for undue quantities of blood. In my judgment this man required but one ligature around the veins returning from the testicle. Some cases require as many as three ligatures, one near the inguinal canal, another near the globus major, and a third underneath the globus minor. Twisted silk should be employed, disinfected, and tied as tightly as your strength will permit. This case is a practical demonstration of the moderate amount of reaction which follows the operation. Frequently there is more exudation and inflammatory deposit about where the vein has been tied, the tumor amounting in size at times to that of an English walnut. But it does not suppurate. I have seen but one case in which suppuration resulted among probably a hundred operated on, and in that one the ligature came away. In another there was some serous exudation for a few days, but it did not go on to suppuration.

We will now pass to the subject for our especial consideration to-day, and presumably we have an illustrative case before us, although I have not yet had opportunity to examine the man. The subject is that of internal urethrotomy for anterior stricture of large calibre, not of small calibre. It has become customary to speak of urethral symptoms, or symptoms having their origin in the urethra, as if they were diseases. Now, a symptom manifesting itself from the urethra is no more a disease than a symptom in any other part of the body. If someone whose friend had a cough should ask you what is good for a cough, you would answer that there is no such disease as cough. But if another man whose friend had a gleet should ask what is good for a gleet, you would, according to the modern method, reply that he should have his strictures cut. It has become the practice in cases of gleet to liberate the urethra of any tight points or narrowings in its course with the view of thereby curing the gleet. But in my opinion such teaching and practice are not sound. You might as well say that the proper treatment of cough is the use of cod liver oil, or of iodide of potassium, going

South, etc. There is no such disease as cough, and there is, truly speaking, no such disease as gleet. A man may have a chronic urethral discharge, called gleet, due to a tuberculous condition of the kidneys, or disease of the seminal vesicles, or prostatic disturbance, etc., and the mistake be made of dividing certain narrowings of the urethral canal which are altogether physiological for the cure of the gleet. These narrowings are found: at the orifice; within a third of an inch of the orifice, the distance varying somewhat with the variations in the size of the penis (this is sometimes called the false meatus); another distant between two and four inches from the orifice; another at the bulbo-membranous junction. In other words, the urethra is narrow at the meatus, then large, then narrow, then large, then narrow, and again large. It seems to me the reason for these narrowings is physiological. The orifice is narrowed in order that the individual may be able to throw a smooth stream, not a scattering one, and clear itself. Inside of the smaller orifice there is a sinus which corresponds to the expansion of the glans penis, and is found wherever there is much erectile tissue about the canal. Then the urethra is narrower until between the second and third inch from the orifice, when it becomes further narrowed; after which the sinus of the bulb is reached. Here the canal is surrounded by the greatest amount of erectile tissue, and a distinct pouch exists, the object of which is to catch the last few drops of urine expelled from the bladder at the close of micturition. The spasmodic contraction of all the muscles which bear upon the sinus of the bulb forces these last drops outward, clearing the meatus in a fine jet. The levator ani, the perinei, the pyramidal, the circular muscles in the membranous portion of the urethra, all act in clearing the canal of the last drops. In doing this a wave of blood passes along the corpus spongiosum from behind forward, and is noticeable in the expansion of the glans during erection; when the organ is flaccid it is not observable.

You have before you a person with gleet; you are aware this may be due to various causes. On passing a bulbous sound along the urethra a narrowing is felt at certain points in the pendulous portion, already noted, and the question will arise, Shall you cut or not? You may cut the constricted points if you choose. It is the fashion now to do so. It is alleged by some to be the proper treatment of gleet to relieve the urethra of points of contraction, and to make the canal of uniform calibre throughout as far down as the membranous portion. That this results in the cure of a certain number of cases of gleet is unquestionably true, the reason being that many gleets depend upon a granular condition of the urethra which requires for its cure pressure, and this cannot be exerted by means of the sound between narrowed points. If, then, granulations exist in the canal, requiring pressure for their cure, and the orifice is found small, divide it, and then if there be disproportionate narrowing in the pendulous urethra, divide that also, that you may be able to pass a sound of sufficient size to make the desirable amount of pressure; for the greater the pressure in such cases the more rapid will be the cure. Pathological narrowing may exist in the pendulous urethra caused by traumatism, peri-urethral abscess, follicular inflammation, long-continued granular condition, or other inflammatory state; and when present such strictures should be fully divided, after having first rendered the canal anæsthetic with cocaine. But if you find your patient has simply a moderate amount of contraction in the second or third inch of the canal, it will not be necessary or desirable in the majority of instances to use the urethrotome. Such routine surgery is objectionable, and is based on an imperfect conception of the origin of many gleety discharges. I wish to state this fact very forcibly, for I scarcely ever get a patient with a gleety discharge which has existed a year or more (and I see a great many of them from New York and distant points) without his having already been cut in the pendulous urethra two, four, or, as in one case, eleven times; yet the muco-purulent discharge has not been cured. Therefore I repeat that it is a great error to suppose that the narrowing which exists in the pendulous portion of the urethra is always the cause of the gleet from which the patient may suffer. So to regard it, and adopt the knife as routine practice, brings surgery into disrepute among the laity, and it is among the laity that we must maintain a reputation for integrity and correct practice. The routine practice of dividing narrow points in the urethra for gleet is to be likened to the conduct of the plowman who read in a magazine how to write a successful story. Thinking it would be a good thing to write a successful story, he followed the rules given; but his story did not prove a success, and he asked an equally stupid friend how to account for it. The reply

was that he probably had not used the right kind of ink.

Try to discover the origin of the gleet, and locate the trouble which is the cause of its continuation. Sometimes you will be able to do this, sometimes you will not. The case before us may enable us to bring out some diagnostic points. I have not yet examined him, but he is said to have gleet. I am further told that he has a narrowing in the anterior urethra, and the question has arisen whether to cut it; and if the answer is affirmative, why? The operation itself, should it be determined upon, will occupy very few minutes.

I requested my assistant to collect the patient's urine, have it passed in two parts, the first passed collected in one glass graduate, and the last part in another by itself. But this has not been done, for the patient has just passed his water. Consequently I shall now be unable to demonstrate the point which I had intended to do, and which is necessary in making an exact diagnosis. It is a most extraordinary fact that a man will come all the way from Rochester or San Francisco to be examined for a urinary trouble, and perhaps be obliged to return by the next train; yet just before reaching the doctor's office (and being perhaps unduly nervous), he will go around a corner or to some water-closet and pass his urine. Having emptied his bladder, the doctor cannot obtain a specimen of his urine, and is unable to make a diagnosis or to treat the case thoroughly. If the patient has time he may return again, or sit in the office a couple of hours until his kidneys have time to secrete more urine, otherwise one valuable diagnostic point may be lost.

After waiting for some minutes, this patient has been able to urinate again, and has passed more than an ounce of water in one vessel and a less quantity toward the close of the act in a second vessel. The first portion washed the urethra, is muddy in consistency, looking like cider or mutton-broth or chicken-tea. This color signifies that it is mixed with some solid substance which renders it more or less opaque. The part passed last is clear. If a man comes to you and passes such urine as this which has washed the canal, while the last part is clear, you may conclude that his trouble lies in the urethra anterior to the neck of the bladder. Why? Because if the pus formed in the vesical neck or above it, some of it would collect in the bladder, and pus coming from the kidneys or bladder is mixed with the whole amount of urine, so that that passed last is as perturbed as the first.

We may safely say, then, that the cause of this man's gleet is either in the anterior urethra or in the grip of the membranous urethra, and does not involve the prostatic sinus.

A second point relates to the shreds contained in the urine, for a man with moderate gleet always passes shreds. They look like tufts of cotton floating about in the urine, or else like long, thin filaments. When of the former character they come from the deep urethra, and when of the latter character generally from the anterior urethra. In this case we find some relatively broad while others are relatively long.

If there is considerable secretion of pus, say one drop to be found most of the time at the meatus, and another ready to be squeezed out, it may all come from the anterior urethra. If a man says he has only a little gleet, sufficient to gum over the meatus, without staining the shirt, the focus of disease may be the deep urethra, some of the pus remaining in the canal to be washed out with each flow of urine. In such case the chunky shreds in the urine will preponderate over the linear shreds and there may be more or less free pus. If the patient forms one drop of pus an hour in the anterior urethra it will be sufficient to stain the shirt, and if this amount is formed and the shirt is not stained it is because the secretion comes from the deep urethra, and remains in the prostatic sinus or flows backward into the bladder, and then to cut the anterior narrowing in the canal will not relieve the gleet.

When a man comes to you with gleet, ask him how often he passes water. If not oftener than five or six times a day it is normal. No perfectly healthy young man gets up habitually to pass water at night. Of course he may do so occasionally, as after drinking excessively of fluids, or awake with a priapism and rise to urinate to relieve it. This patient says he passes water five or six times a day and once at night. I venture to say that if he passes water regularly once at night he has an irritation in the deep urethra, which would correspond with the chunky shreds which we find in the urine first passed. If he urinates once at night he probably does so oftener than five times a day, say eight or more times.

Thus far we have obtained circumstantial evidence that our patient has a gleety discharge, the origin of which is in the deep urethra and some of it in the anterior urethra as well. But we will examine him

with the sound to learn whether there is not also difficulty in the anterior urethra. Since he has just washed out his urethra by urination, any pus lying in the anterior urethra must lie there as a soft scab upon a granular surface, and this may be scraped away upon the shoulder of a bulbous sound. His meatus being rather small, we can introduce a bulbar instrument of hardly sufficient size, and it will be better to substitute the urethrameter of Dr. Otis, which can be turned up after passing the meatus to form a bulb. Pass the instrument down into the sinus of the bulb. Screw it up until the patient is sensible of the pressure. Then withdraw it gently screwing it down as it reaches the narrowed areas. On withdrawal it will bring away a clot of pus, often tinged with blood if the narrowed areas are also in a granular condition. If that is the case you have corroborative evidence of the filament of pus found in the first urine passed. But if the bulb comes away clean, without either pus or blood stain, the patient does not show undue sensitiveness at the points of narrowing in the pendulous urethra, and the shreds contained in the first urine passed are not long and filamentous, but chunky, you may conclude that the discharge comes from deeper down, and that division of the anterior narrowing will not cure it.

Of diagnostic importance is a microscopical examination of the shreds passed with the first urine. The chunky shreds, which come from the posterior urethra contain besides pus cells, ovals cells which are from the deep portion of the urethra and the neck of the bladder, and the whole is bound together by a colloid material. Sometimes casts of the prostatic ducts are present, amylaceous corpuscles, perhaps spermatozoa.

Regarding the measurements of the penis and urethra, the rule given by Dr. Otis to determine their relative size is a good one; I know of none better, but I do not agree with him as to the necessity for making the urethra of uniform size throughout. When it is necessary to perform internal urethrotomy you may cut safely to the limit which Dr. Otis's rule calls for, and sometimes it will even be necessary to cut more deeply in order to divide all the constricting fibres. But many people get well of a gleet without having the canal brought up to the size alleged to be called for by the circumference of the penis, and indeed many people go through life with considerable narrowings of the urethra without any symptoms referable to the penis. Dr. Weir has examined the urethra in cases of fœtuses removed from the womb of the mother, and found contractions at the orifice and in the pendulous portion. Such contractions must, then, be physiological. Dr. Weir also took casts of the urethra in the normal and in the diseased state, by injecting plaster or wax into the canal and after it had hardened cutting it out, and in all instances the canal was found to be somewhat like the trachea, composed of small rings, more marked anteriorly and in the middle portion. You can divide the urethra internally up to any point you choose, until a sound will pass in and out perfectly smoothly, encountering no obstruction, yet when you pass the bulbous sound, one a little larger than the ordinary sound which goes smoothly down, you will find it give the sensation as if the canal were ribbed.

I once yielded to the solicitations of a young man who suffered from all sorts of neurotic disturbances to divide his urethra on a number of occasions, but never got to the point where the bulbous sound in passing down would not bump over points of apparently fibrous structure. Finally I concluded these operations had been carried far enough, and refused to do any more cutting, but he insisted that there was a constriction which needed to be divided, and being asked how he assured himself of it, he said he could feel it, and taking out his penis he opened the orifice, put his finger into it, and said "here it is!"

Recently the ribbed condition of the urethral canal has been demonstrated beyond peradventure by the aero-urethroscope of Antal. A urethroscope is an instrument through which one can look into the urethra, and an aero-urethroscope is one which combines distension of the canal with air. By its aid one can see the semicircles and circles of fibrous material which are present as far as vision extends. The aero-urethroscope further demonstrates the normal contractions to which we have alluded.

In view of the fact that this man's urine contains some filamentous shreds, indicating that they come from the pendulous portion of the canal, that there is sensitiveness at the narrowing posterior to the glans, facts pointing to some inflammation at that point aside from that which evidently exists in the deeper urethra, and that the bulb comes out stained with both pus and blood, we will divide the narrowing in the pendulous urethra, and also enlarge the meatus to enable us to pass the sound. The deeper urethral trouble must receive attention later.

After cutting, the parts need not be disturbed for three or four days, and after that the sound should be introduced down to the membranous urethra, but not through it, twice a week. Some deep injections will probably be required in this case before complete recovery will take place.

COMMUNICATIONS.

TRAUMATIC GANGRENE.[1]

BY THOMAS H. MANLEY, M.D.,
NEW YORK.

Mr. President and Fellows: I am led to present an article on traumatic gangrene because it has been my fortune, during the past few years, to see in and out of hospital many genuine cases of this disorder; and while there has been nothing unusual which each case assumed, it may not be without interest to record four or five of them, and afterward dwell on the causes, consequences, and treatment of mortification. In doing so I shall aim rather to be plain and practical than to offer too much theory and speculation.

The discussion of this phase of disintegration cannot fail to be of great interest to the general practitioner, as well as to the surgeon; especially the former, who often is compelled to decide questions of saving life or limb, without the opportunity of consulting with the experienced surgeon.

Traumatic or moist gangrene of a limb is rarely seen in general practice, and very seldom in a well-conducted hospital. Usually when a limb is so crushed or mangled that saving it appears impossible, the spontaneous destruction of the part is frequently anticipated by amputation or excision; and besides, nowadays, wounds and injuries are for the most part so intelligently treated, that death of a part seldom occurs. Hence, the reason why this rare and peculiar sequel of a wound may, by its insidious development and often very rapid course, escape the notice of the medical attendant until it is too late to spare a limb, which might otherwise have been saved.

When it is found, however, that inflammation has ceased and mortification begun, we are confronted with a most serious question, namely, the question of amputation *while gangrene is in a spreading state.* To its consideration, later on, I shall request your attention; for on its wise and judicious settlement will depend, perhaps, not only the life of the patient, but also his future usefulness. I am pleased to be able to report four or five typical cases which have recently come under my immediate care. They are of much interest, for each one presents phases of gangrene seldom met with, and, I believe, little understood, even to-day.

My first patient was a middle-aged man, mortally bitten by a rattlesnake. He was brought in by the ambulance, to Ninety-ninth Street Hospital, at midnight on June 12, 1885. During the evening of that day he had been exhibiting his reptiles in one of our parks. After supper, according to the announcement, he gave a performance in his tent, which consisted in calling the snakes out of their cages and putting them through various movements. While doing this, one which he had teased with his whip suddenly turned, and with a vicious snap sunk his fangs deeply into his trainer's forearm. The unfortunate fellow, who was a vigorous and muscular man, became faint and dizzy; he sat down, and tried to get up, but fell on his knees. He soon had chills, with cold extremities, and his strength entirely gave way. Whiskey was administered in large quantities and heat applied to the extremities. During this appalling collapse, his mental faculties remained intact, and, though he could neither speak nor move, it was apparent that the mind was unclouded. At this time his pulse was 130, the features sunken and of a peculiar cadaverous expression, the pupils dilated, and the eye of a bright, unnatural lustre. Such is the report of the case, as given me by Dr. G. E. Spaulding, our estimable House-Surgeon, at that time on duty.

The case was first seen by me the following morning, when all hope of saving the injured arm was abandoned. At this time the forearm that was bitten, and all the tissues up to the shoulder, were dead to sensation and immensely swollen; the skin was of a yellowish-gray color, the fingernails black, and the whole limb immovable. In the immediate vicinity of the puncture, there was an area of marble whiteness about the size of a half-dollar. The man was evidently sinking, and as the infection had extended beyond the shoulder-joint nothing could be hoped for from amputation, even if he would survive the shock of operation. From his admission into hospital, nothing was neglected that

[1] Read before the New York State Medical Association, Oct. 10. 1888.

would sustain his strength. Alcoholic stimulants were freely given with ammonia, camphor, and opium, but without avail; he died in the morning at 10 A. M., eleven hours after his admission.

This case demonstrates how rapidly gangrene from the bite of a venomous reptile may spread. Within six hours after the infliction of the bite, the whole arm, including the shoulder, was in a state of sphacelus—thoroughly dead, dark, and withered; there were blebs on the skin, scattered about from the finger-tips upward. The skin was denuded here and there, where it happened to be rubbed in handling; the whole arm emitted a foul, sickening odor. A most painful feature in the case was that, while death was rapidly creeping on and the limb was rapidly decomposing, the mind was untouched, and the poor fellow was anxious that his life might be spared.

It seemed to me that, with appropriate measures applied promptly on the reception of the injury, this man's life might have been saved: if the bitten part had been freely dissected out, allowed to bleed, and thoroughly cauterized with the hot iron, before the poison had been diffused into and through adjacent tissues, paralyzing the nerves and destroying the circulation. It was sometime, however, before an ambulance was called; then the poison had entered the general circulation and little could be done. A *post-mortem* could not be obtained.

My second patient, though he got off with his life, had to part with an arm. This case also illustrates the speedy onset of gangrene, and the sudden transition of inflammation to mortification, and what may be sacrificed by oversight or even a few hours' delay.

The man was 38 years old, a tinsmith by trade, living a regular life; he never dissipated nor abused himself, but was generally in good health. He lived in a tenement house, the first floor of which was occupied as a butcher's shop.

On a very hot night in July last year, he left his bed at about midnight, in his night-clothes, and went to the window to make himself more comfortable. The window-sill was quite near the floor.

He only intended to get a little fresh air, to cool off and then return to his room; but, overcome by the weariness following upon a day's hard toil, he was soon asleep. How long he slumbered he hardly knew, but it must have been some hours, for it was dawn when he was discovered. While asleep, it seems, he shuffled about in his chair, lost his balance, and went out through the window. He first struck on the awning, and was awakened by the fall. He then rolled over and over, quickly gliding toward the flags below; but in the course of his rapid descent, his right arm, at the flexure of the elbow, on the inner side, was transfixed by one of a row of butcher's hooks, which tore up all the tissues to the bone, and was only arrested at the wrist by the tough ligamentous tissues which form that joint. Here he hung suspended for nearly half an hour, when his loud shrieks brought an officer, who released him from his perilous position.

On examination of the wound, on his admission to the Harlem Hospital, by Dr. Lewis, the House-Surgeon, there was very little hemorrhage, though the brachial artery was torn completely across just below where it emerges from under the bicipital fascia. The hand was quite cold, with no evidence of circulation. The wound was immediately dressed, beginning with the ligation of the large artery, and thoroughly irrigating the furrow in the tissues. Drainage tubes were inserted and the wound closed from end to end with cat-gut sutures. Iodoform was freely sprinkled over the dressing; Gamgee absorbent dressings were applied, and the whole supported, and heat maintained, with hot bottles.

I saw the patient for the first time six hours after the injury, when I carefully examined the fingers, the only parts exposed, and found that the circulation was fairly re-established.

There was little swelling at this time, and though the hot water bottles had been some time removed, natural heat was yet there. The patient said he had his usual feeling in the hand, complained but little of pain, and looked well.

He passed a quiet, uneventful day. His pulse at mid-day was only a little accelerated, and, with a good collateral circulation, it seemed, after all, that he might soon recover without any serious detriment to the use of his arm.

The morning dressings were undisturbed, and things allowed to remain as they were. Toward evening, the temperature suddenly went up, and he became thirsty and restless. The thumb and fingers underwent considerable swelling and increase in heat, and he complained of severe pain along the course of the wound, extending into the fingers. It was now evident that collapse had passed away, and re-action set in, and that nature was attempting restoration. I had antici-

pated this at my morning visit, and directed the House-Surgeon, if there were much swelling, to release the sutures and loosen the dressings, which he did, much to the relief of the sufferer. As day passed into night, he became more and more uneasy, continually complaining of a severe burning pain extending from the hand to the elbow. His pulse, at midnight, was a hundred and thirty beats to the minute, hard and bounding, and the thirst persistent.

With the advent of early day, he slept three hours, and felt much more comfortable. There was, however, great bodily weakness, so that he could hardly move in bed. In going through the wards, at about 11 o'clock, I was much surprised at this man's changed appearance, and concluded at once that the wound was not doing well, though the House-Surgeon assured me that, two hours before, everything appeared to be progressing favorably. The patient, strange to say, said he felt first-rate. He was immediately removed to the surgery, where an examination was made. The fingers, hand, and arm, to and above the elbow, were found stone-cold, discolored, puffed, and boggy—in fact, all the tissues here were dead and becoming gangrenous. The scalpel could be plunged in anywhere, up to within six or eight inches of the shoulder, without evoking the slightest sensation. The dividing line between the living and dead tissues, though not visible to the eye, could be more or less defined by the circulation and sensation. Up to the insertion of the deltoid muscle, the parts were quite devoid of life, but at this point there was a striking difference in the color and consistence of the blood let out on incision.

Now, we had before us a case of great gravity, one which emphasizes what I said in the beginning of this paper, of the insidious and treacherous nature of this disease, and the serious developments which may follow in a wound, even under the most intelligent treatment. Here, too, came up that question, At what stage is operative interference justifiable? Shall we wait for nature to separate the healthy from the diseased, or shall we take time by the forelock, and do that by art which nature only tediously and imperfectly performs?

In the present case it seemed to me that gangrenous infiltration was rapidly spreading upward, and that if it were allowed to creep but a few inches further, and involve the shoulder-joint, relief by operation would be impossible. Consent having been given to amputate, ether was given, and the limb removed at the shoulder-joint. I shall later on describe more fully the condition of the parts at the time of cutting. The patient made a good recovery, the wound healing by primary union; he left the hospital in good health, six weeks after his admission.

My third case, like the second, well illustrates the imperative necessity, at times, of amputating while gangrene is spreading, and teaches besides the important lesson that a comparatively trifling injury may, if not properly treated, end in loss of a limb, or even of life.

The patient was a man forty years old, in sound health, by occupation an engineer. On January 12, 1888, while ascending an elevator, he had the big toe of the right foot crushed between the sill of a door and the platform of the elevator. A practitioner in the neighborhood was called in and removed the nail, which was partly detached, and the third phalanx, taking his flap from the under surface of the toe and bringing it forward to the point at which the bone was disarticulated; the dressing was with all antiseptic details. A week after the accident, I was invited by the wife to see the case, but declined, except with the regular attendant. A few days later, a consultation was held, when it was decided to remove the third phalanx of the adjoining toe. As this operation was followed by the same torturing pain, and the man could neither eat nor sleep much, and was daily losing flesh, his wife insisted that I must see her husband. The surgeon in attendance consented. This was three weeks after the injury. It was about noon when I saw the case in consultation for the first time. At first sight it seemed to me that the foot was surely doomed. It was immensely swollen on the inner side, œdematous and cold. On critically examining the parts I found more or less warmth in the three outer toes, and in the external portion of the foot. I advised immediate amputation of the affected parts, which was done one hour later. All the phalanges of the big and middle toes and their metatarsal bones were found necrosed, the fleshy parts were broken down, disintegrated, and soaked in a sero-purulent liquid of vile odor.

The most difficult feature in the operation was to decide exactly how far to cut, in order not to include contaminated tissues. We gave the patient the benefit of the doubt, and removed as little as possible. Though we used no tourniquet, we had little hemorrhage. This, I feared, was a bad omen, as we all know how extremely vascu-

lar this region of the body is. The morning after amputation the doctor and I saw him together. At this time the remaining part of the foot looked anything but encouraging. Large blebs had formed on the dorsum of the foot; the swelling remained, and what was left of the foot was rather numb to the touch. As the people were rather poor, and the apartment not the healthiest, it was decided to send him to hospital. Accordingly, the same day he was admitted into one of my wards in the Harlem Hospital. I immediately sent for Professor F. S. Dennis, one of the Visiting Surgeons, for his advice in the case. He responded promptly, and at 5 P. M. he, with Dr. John G. Truax, saw the case with me, and advised delay and waiting for further developments. The rapid recovery of the part was amazing. It healed quickly and compactly by granulation, and the patient returned to work just six weeks from the time of entrance to hospital, with a fairly useful foot; and now, though he is a little stiff in his gait, there is scarcely any lameness perceptible.

The fourth case was that of a young German twenty years old, admitted into Harlem Hospital June 2, 1888. His horse had taken fright, and he was thrown from a wagon against an iron support of the Elevated Railroad. When picked up, it was found that he had sustained a compound fracture of the lower third of the radius, with a compound dislocation outward of the articulating ends of the radius and ulna at the wrist joint. On admission to hospital he was suffering considerably from shock. The parts were thoroughly cleansed, irrigated with sublimate solution, the displaced bones reduced, the surface of the wound dusted with iodoform, the Gamgee dressings applied, and the whole supported by suitable splints.

Prof. Dennis, who had charge of the case in its early stages, saw it for the first time, June 3, the second day after the patient's admission. By his direction drainage tubes were inserted, and the most thorough antiseptic treatment instituted. On the third day after admission, he began to complain of pain, the ulnar side of the hand seemed to become cooler, and the skin was of a rather suspicious color. June 6, the fourth day after admission, the hand showed unmistakable evidence of gangrene. The ulnar side of the wrist and hand, and the four fingers on the corresponding side were much swollen and destitute of sensation. His appetite, however, remained good and he slept well. June 9, the date on which I first saw the wound, and resumed charge of the surgery at the hospital, the whole hand from the finger-tips was more or less mortified, with patches here and there, where it seemed some vitality remained. A large slough occupied the palmar surfaces of the hand, extending deeply into the carpal bones. The opening through which the bones protruded had not closed, and their bare denuded ends could be plainly seen. It seemed at first sight that notwithstanding the slight evidence of life remaining in the thumb and index finger, that the only safe and expeditious way to proceed would be to amputate the whole hand. As it would appear that gangrene, having involved all the carpal bones, and the fleshy tissues being in a sloughy state, nothing short of this would suffice.

From my success, however, with my preceding cases, in operating while gangrene was spreading, I decided to try and save the thumb and first finger. When we operated, we found all the phalanges of the three outer fingers, with their metacarpal bones, and all the carpal bones in advanced necrosis. The ends of the radius and ulna were also necrosed and deprived of their periosteum. Everything of a suspicious character was removed; but the thumb and finger were spared.

The process of disintegration here was so rapid and thorough, that one would think the retained members very soon must have shared the same fate as those which were removed.

The wound was treated on general surgical principles and by keeping the arm in a well-padded zinc splint, hollowed out and extending from the end of the finger and thumb to the elbow. The wound healed kindly, though the skin on the preserved members peeled off in the course of recovery. He left the hospital one month after entering it; the wound was well healed, and he had fair use of the thumb and finger.

I ask your attention to my fifth and last case for a few moments because there was a feature in it peculiar to itself, and of very much importance. A youth seven years old, while playing on a coal-car that was in motion, fell to the ground; the wheels passed over the right lower limb obliquely, tearing the skin completely off from the knee to the ankle, and, crushing through the bones of the latter, left the foot hanging by a few torn tendons. When reached by the Ambulance Surgeon, Dr. Curry, he had

bled profusely, and was in a state of shock. He was admitted into the Harlem Hospital on September 3—in fact, since I commenced this paper. Nothing was done with the mutilated limb until the following day, except to secure the vessels and apply dressings. On the second day after his admission he had recovered from shock and the profound collapse, but had a very feeble pulse. The foot was separated from the leg by snipping off the tendons with the scissors; the leg was then again cleansed and bound up. Nothing further was done for five days, except to give the patient stimulants and nourishment, with a view of getting him in condition for operation.

It was now thought that, with the bare ends of the tibia and fibula exposed, the superficial tissues of the limb in a state of slough up to the knee, and his condition fair, though yet with a weak trembling pulse, we might make him more comfortable and rid him of the offending members by an amputation above the knee. The limb might have been removed lower down, but then there would have been no integuments for a flap.

The question to decide was, When to amputate, with reasonable safety? my own experience being that very young children do not tolerate amputations well. At this time, the exposed tissues had begun to granulate, the only one of the five cases in which this occurred; the line of demarcation was well defined, commencing in an oblique circular form just above the patella, and embracing the entire limb. At the borders of this narrow chasm, the position and consistence of the parts were most interesting to study. On the necrosed side the tissues had a gray, charred appearance; they were withered and shrunken, and, as time had allowed the aqueous elements to evaporate, the slough had become dry and tough. On the other hand, the sound side of this ridge looked remarkably healthy and in striking contrast with the parts undergoing dissolution.

A flap was formed by detaching and turning back the skin at the healthy limit, and removing but a very thin shaving from the border, with a view of securing primary union. The femur was divided about two and one-half inches above the knee joint. After amputation the flaps were sutured, drainage tubes used, and the stump put up in the usual dressings. Not more than a drachm of blood was lost. It was more than four hours before the patient regained consciousness, and he remained very feeble, never really rallying from the operation, and died the following day, about thirty hours from the time he reached his bed. The amputated limb was carefully examined and found sound down to the protruding ends of the bones. I saw no object in trying to save the limb when it was entirely denuded of integuments; and skin grafting, which forms at best but a sort of cicatricial tissue, is almost useless as a covering to a movable joint like the knee.

Such was the melancholy ending of my last case. The child's life, I am confident, should have been saved, and I committed the fatal error of cutting before the recuperative powers were fully established. Everything was to be gained by waiting even a month, and nothing lost; but it is always easy to be wise after the mistake is made. It taught me a valuable lesson, however, and I would warn my brethren of the great danger of operating while the vital processes are at a low ebb. With reference to the foregoing cases, I would respectfully call your attention to the varieties of traumatic gangrene, and to its causes, consequences, and treatment.

In the beginning, moist gangrene must be divided into two kinds, the spreading and the non-spreading—that in which the limit of death is sharply and accurately defined by a dividing line, in a very short time after violence is sustained. But it must be admitted that this dividing line is no criterion as to the depth of mortification. The first kind is that in which the line of demarcation is wanting or not well marked, which I have chosen to designate the spreading, inasmuch as the gangrene starts from an insignificant injury or very limited solution of continuity, and extends rapidly from the periphery toward the body.

The causes of gangrene are obscure in many instances. Pathology has done little to clear the way to a better understanding of morbid process in gangrene; and, after all, we have to lean on our own experience for guidance in treatment.

Sometimes its development is unavoidable. We cannot predict how extensive or destructive an injury will be. No one can explain why a trivial hurt in one case leads to most serious consequences, while in another the extent of mutilation is alarming, and yet the limb recovers perfectly, with little or no constitutional disturbance, and no loss of function. This is the mystery which it seems all time will never reveal.

Inflammation is the most active factor in the production of moist gangrene. In all

my recorded cases except one there was active inflammation preceding mortification. In only one, in which the toxic irritant was immediately applied, the limb succumbed with the diffusion of the poison, which seemed to multiply in intensity in its progress. The laceration or obliteration of a large blood-vessel contributes its share toward the destruction of a part by cutting off its nutrition; but that this alone will lead to gangrene in a healthy person, I am inclined to doubt.

We all know that there is scarcely a single vessel in the body which may not be closed by the ligature without the peripheral parts being in the least endangered. Even in one case of gangrene of the ulnar side of the hand here reported, it would be hardly rational to suppose that even if the entire ulnar artery were destroyed, it alone would occasion mortification; as we all know that the collateral circulation in the forearm is good, and besides, there is the freest kind of anastomosis between the ramifications of the radial and ulnar arteries, in the superficial and deep palmar arches.

Injury to a nerve may be transmitted to a large trunk, and from there affect a large area; and it is entirely reasonable that a nerve filament may undergo death, and then in turn all the distant parts supplied by the common trunk share the same fate.

We may have gangrene of various extent, and sometimes its course is remarkably fickle and erratic; as when it destroys the skin only, without affecting the subjacent tissues, and when it destroys the latter and spares the former. Blocking of the blood-vessels will not explain this; so that we must look to a deranged or interrupted nerve-supply to account for it. Excessive or improperly adjusted pressure, and neglect or ignorance of wound treatment, are often responsible for gangrene.

We now come to its treatment, and this is the part of the subject in which I am especially interested. It may be divided into preventive, conservative, and operative; with the latter I am chiefly concerned. For prevention, use measures which will subdue inflammation. The modern enthusiast in antiseptics would have us believe that these, when rigorously applied, render inflammation impossible. If we should unconditionally subscribe to this doctrine, then it would be idle to discuss other means of relief; but there are some skeptics among us who are not quite ready to throw aside remedies which have stood the test of centuries.

Cleanliness, soothing applications—warm or cold, according to the comfort they give—rest, good fresh air, with light wholesome diet, contribute toward a favorable issue. Drugs are not to be despised. The best are those which allay pain and those which act specifically in subduing inflammation. For the latter purpose mercury has no equal, either applied locally in the sublimate douche, or given internally.

Of course, if I believed in the natural tendency of disease to recover, I could not consistently advise any drugs; but I believe this do-nothing theory has cut short many valuable lives; that disease never comes except to destroy; and that our province is to apply our art so as to limit or arrest the progress of the disease.

If inflammation will develop in a case of gangrene in spite of our efforts to control it, we may often modify its violence by free blood-letting in the vicinity of the congested parts, either by free incisions or punctures, the bleeding to be encouraged by warm, moist applications.

If inflammation terminates in mortification, what are we to do? When is interference by the knife justifiable? Shall we do by art that which nature very slowly accomplishes? Is it hardly conceivable that the attendant will stand idly by and see a limb slowly but steadily perishing, the deadly process propagating itself upward toward the vitals? Shall we amputate in spreading gangrene? These are questions which may be forced on the practitioner at any time; for it must be borne in mind that an extensive mortification may arise from a simple wound under certain circumstances which may involve the loss of a limb.

Among the great surgeons of the early part of the present century there was much difference of opinion about the propriety of amputating while gangrene is in a progressive state. Sir Astley Cooper gave the great weight of his authority to the side which advised delay till more or less detachment of the diseased from the living tissues was evident. On the other hand, both the world-renowned military surgeon, Baron Larrey, and Mr. Guthrie, gave the most cogent and convincing reasons for immediate interference.

Larrey said: "That in cases of mortification arising from external injuries, notwithstanding what practitioners or writers may say to the contrary, we should not hesitate about promptly performing an amputation as soon as the necessity of doing the operation is established. There is no reason to

apprehend that the stump will be seized with gangrene, as in the spontaneous variety which has not ceased to spread, because the traumatic mortification, after having arisen from a local cause, is only propagated by absorption, and a successive affection of the textures of the parts by continuity of vessels. Amputation performed in a proper situation arrests the progress and fatal consequences of the disorder."

We must be positively assured that a limb is actually gangrenous before we resort to cutting. This can usually be easily determined by its condition, the absence of circulation, the discoloration and puffiness of the skin, and above all by its icy coldness—that state of the tissues in which Dupuytren proved by experiments that the temperature, for some inexplicable reason, is lower than in the dead body.

The exact point or locality at which to enter with the knife when we have decided to amputate—where to sever the parts so as to get rid of the defunct and spare the living—is to the inexperienced a very difficult matter to decide. To the conscientious surgeon, as well as to the unfortunate patient, it is a most serious affair; as we all know the inestimable value to the wage-earner, not only of a limb, but of every joint, no matter how small. On theoretical grounds, we should take no chances, but go well beyond the suspected tissues. My experience, however, has taught me to be extremely conservative, and include in the flap even some of the tainted part, rather than go too far up into sound tissues, especially when a joint is involved.

In my case of mortification of the whole arm, in consequence of external violence, and which was successfully amputated at the shoulder joint, the skin of the limb was greenish and livid, but high up the cuticle was not detached. The cellular substance was distended with air and a discolored sanies; and its appearance was not quite natural when the incision was made. It was yellowish and anasarcous; small effusions of blood were observed here and there along the course of the nerves as high as the point of amputation. All the soft parts were discolored and livid, and a frothy reddish fluid issued on incision.

As this case had a most favorable termination, it clearly proves that humid gangrene in the healthy subject from severe local injury, which so rapidly affects a whole limb and reaches the trunk in a few hours, must constitute an exception to the older maxim: "that amputation must never be performed till the line of demarcation is well defined."

To sum up, it will be noticed, in the first place, that all the patients were males; that there was a local *rot* without a general infection in all except one. The first case was most remarkable for the swift and appalling virulence, and almost immediately lethal action of the bite of the snake. In the second, though collateral circulation was established after the ligation of the brachial artery, mortification quickly supervened, and was abruptly arrested in its march by carrying the knife through the invaded tissues. The third case illustrates what a serious condition may arise from a trifling injury; while the fourth shows that we should use all our endeavors to save every inch of tissue which shows the least spark of life. The fifth case was lost, I believe, through acting without the deliberate judgment by which the surgeon should be influenced in every extensive operation.

CASE OF ANTHRAX.

BY WILLIAM N. FERGUSON, M.D.,
PHILADELPHIA.

I desire to call attention to a most deadly malady, rarely seen and recognized in practice, but one to whose virulent contagion many workmen in our large cities are sometimes exposed. This disease is anthrax.

The patient, F. N., was a "picker" in a manufactory of hair and bristles, who was exposed to the dust of the machine-picker as it separated the bundles of hair. A slight abrasion on his neck, supposed by him to be caused by the rubbing of a high collar, became the open door to the entrance of the poison. Friday, November 23, he felt unable to attend to his work; he had headache, chill, general malaise. His neck began to swell at the seat of the abrasion. He gradually became worse, and on Sunday morning at 8 o'clock he sent for medical advice. I was at once struck with the enormous size of his neck and the depressing effect the disease had already produced on a man of evidently strong physique.

On closer examination I found, on the right side of his neck, about an inch above the clavicle and on the posterior border of the sterno-cleido-mastoid muscle, a spot about one-half inch in length by one-fourth in width and concave on its upper surface; the centre of this area was occupied by skin thrown into a number of puckered folds,

markedly yellow beneath. Around this spot was a sharply defined area, brilliant rose-red in color, and about one-sixteenth inch in width; there was no hardening to be felt. From this spot the brawny swelling had progressed as though all the tissues of the neck were infiltrated with serum; it was not erysipelatous in appearance. His general look was that of a man stricken with a fatal disease; the pulse was feeble and frequent; respiration impaired by pressure on the air passages.

The treatment ordered was a large flaxseed poultice to the neck, and internally a mixture of chlorate of potassium and tincture of the chloride of iron, with stimulants.

Six hours afterward I was sent for hurriedly and found the patient had been having severe attacks of dyspnœa, and that he was in a state of collapse, with ice-cold extremities and no radial pulse. The swelling in the neck had increased to such a degree that the right shoulder began to enlarge. The patient was conscious but complained only of increased paroxysmal dyspnœa. Hot bottles to the feet and legs with a mustard plaster to the præcordial region were applied, and a consultation was requested.

Half an hour afterward Dr. H. A. Kelly met me in consultation in the case and concurred fully in the diagnosis of anthrax.

Carbonate of ammonium and whiskey were prescribed to stimulate the circulation, but the patient rapidly sank and died about 6 o'clock, ten hours after I had first seen him, and sixty hours after the local inoculation.

His occupation as a worker in hair and bristles, the rapid and enormous infiltration of the tissues, the constitutional symptoms, and the sudden collapse in a strong robust man, to my mind made a clear diagnosis of a case of anthrax.

—Dr. John R. Frayser, whom the *Memphis Med. Monthly* calls the "Nestor of Memphis Medicine," died in that city Oct. 26. He was born in Cumberland Co., Virginia, in 1815, and was graduated from the University of Pennsylvania in 1834.

—On account of ill-health, Dr. William A. Edwards, Instructor in Clinical Medicine in the University of Pennsylvania, has been obliged to leave Philadelphia, and will shortly remove to Southern California. He has had charge of the ward bedside instruction in the University for the past eight years.

ASPIRATION OF CEPHALHÆMATOMA.

BY F. H. PATTON, M.D.,

SURGEON TO THE NATIONAL MILITARY HOME, DAYTON, OHIO.

The following case seems to me of some interest as illustrating the advisability of performing an early aspiration for the relief of cephalhæmatoma resulting from violence.

My son R., aged 15, fell from a 56-in. bicycle on his head, August 7, 1888. I saw him almost immediately. He was entirely unconscious from shock, and remained so for an hour or more. There was immediately after the fall a large hard swelling with contusion of scalp over the coronal suture on the right side and a blood tumor with clearly defined edges over the left parietal bone, but no contusion of the scalp here. The boy made about the ordinary favorable recovery from severe concussion, but was in a state of hebetude, with headache and some vomiting, for several days.

The point of interest in the case was the very rare cephalhæmatoma. In this case the blood was probably beneath the pericranium, as the tumor was circumscribed from the first and bounded by the sutures of the parietal bone. There was a diversity of opinion among my professional friends who saw the case, as to treatment. All agreed to wait a week or ten days for evidence of absorption. After the lapse of ten days with no diminution in the size of the tumor, aspiration was discussed. It is surprising how indefinite authors are as to aspiration in such cases. Nancrede in Ashhurst's Encyclopedia says: "If the swelling persists, aspiration may become necessary." Wyeth does not mention aspiration as treatment, except when a serous cyst results. I might mention others as unsatisfactory. At the expiration of twelve days the tumor, in my son's case, was aspirated, and ten fluid drachms of blood were removed. A firm compress was applied over the seat of the tumor for seventy-two hours, when all the remaining fluid had been absorbed, and there was no further trouble with the tumor. In a similar case, I should aspirate sooner. Under proper precautions there is scarcely any danger of carrying septic matter or air into a tumor of this character, and I certainly should prefer this chance to anxiously awaiting the result of the slow process of absorption, with the constant dread of suppuration or the formation of a cyst.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, November 28, 1888.

The President, J. Solis-Cohen, M.D., in the Chair.

Dr. William Hunt read a paper on

Diabetic Gangrene,

in which he first referred to the vast literature devoted to diabetes and the singular fact that the references to gangrene in connection with it are very meagre. The best studies of diabetic gangrene are to be found in French, especially prior to 1868. Peyrot reports 39 cases and there are 101 cases in current French literature, most of them in the *Union Médicale*. Dr. Hunt gave a brief account of ten of these cases, most of which were in males, and among which mental causes were common. He then spoke of the valuable paper of Marchal, who reports 133 cases, of all sorts. Gangrene *per se* occurred in 57 of these 133 cases.

Dr. Hunt does not think that diabetic gangrene starts from an injury; and as regards microbes, he thinks that, in gangrene as in other diseases, they are to be found where disintegration of tissue provides the proper soil for them. König's paper on this subject was mentioned, and his conclusion that amputation should be performed when, in spite of antiseptic and anti-diabetic treatment, the patients grow worse.

Dr. Hunt then spoke of the scanty references to the subject to be found in text-books, even in systematic works on surgery, both in this country and in England, and regretted that it had received so little attention. To determine if possible how many cases of diabetic gangrene had been seen in this city, in which examination of the urine had been made and the result recorded, he sent out three inquiries to those whom he supposed most likely to meet with the disease.

In reply to his first inquiry whether or not the observer had noticed gangrene in connection with diabetes, he received thirty answers. Seven observers had seen no cases, and twenty-five reported a total of sixty-three cases. The age of the patients was usually above 50 years, though one case was noted in a young man 19 years old. The sexes were about equally affected—24 women and 25 men. The most common seat of the gangrene was in the lower extremity below the knee.

The second inquiry concerned the relation between diabetes and phthisis, and whether or not gangrene of the lung had been noted in diabetic patients. The answers to this question showed that most observers could not demonstrate correlation of the diseases from their own experience. Dr. Tyson, however, had noted eight cases of phthisis in 55 diabetic patients. Dr. Agnew had met with one case of gangrene of the lung. Dr. J. C. Wilson had also seen one. Dr. Osler had had two patients die of phthisis and one with gangrene of the lung. Only eleven deaths were attributed to phthisis in 143 cases of diabetes, including those from Dr. Hunt's practice. Dr. Hunt thought this result noteworthy. He then referred to the statements bearing upon the relation of diabetes to phthisis to be found in the books of Roberts, Fagge, Flint, and other authors, among them Blau, whose summary of the literature of the subject in *Schmidt's Jahrbücher*, Oct., 1888, was specially mentioned.
